We have systematically investigated low-frequency noise (LFN) in AlN/AlGaIn/GaN metal-insulator-semiconductor (MIS) devices, where the AlN gate insulator layer was sputtering-deposited on the AlGaIn surface, in comparison with LFN in AlGaIn/GaN Schottky devices. By measuring LFN in ungated two-terminal devices and heterojunction field-effect transistors (HFETs), we extracted LFN characteristics in the intrinsic gated region of the HFETs. Although there is a bias regime of the Schottky-HFETs in which LFN is dominated by the gate leakage current, LFN in the MIS-HFETs is always dominated by only the channel current. Analyzing the channel-current-dominated LFN, we obtained Hooge parameters  $\alpha$  for the gated region as a function of the sheet electron concentration  $n_s$  under the gate. In a regime of small  $n_s$ , both the MIS- and Schottky-HFETs exhibit  $\alpha \propto n_s^{-1}$ . On the other hand, in a middle  $n_s$  regime of the MIS-HFETs,  $\alpha$  decreases rapidly like  $n_s^{-\zeta}$  with  $\zeta \sim 2-3$ , which is not observed for the Schottky-HFETs. In addition, we observe strong increase in  $\alpha \propto n_s^3$  in a large  $n_s$  regime for both the MIS- and Schottky-HFETs. © 2014 AIP Publishing LLC. [<http://dx.doi.org/10.1063/1.4892486>]

## I. INTRODUCTION

GaN-based metal-insulator-semiconductor heterojunction field-effect transistors (MIS-HFETs) have been extensively developed as devices for high-frequency and high-power applications, owing to the merits of gate leakage reduction and passivation effects. As a gate insulator, high-dielectric-constant (high- $k$ ) oxides such as Al<sub>2</sub>O<sub>3</sub>,<sup>1</sup> HfO<sub>2</sub>,<sup>2,3</sup> or ZnO,<sup>4</sup> and high- $k$  nitrides having high thermal conductivities such as AlN<sup>5-8</sup> or BN,<sup>9,10</sup> were employed. In the GaN-based MIS-HFETs, low-frequency noise (LFN) will be strongly influenced by the insulator itself and/or the insulator-semiconductor interface, and also by the gate leakage reduction. Although LFN in the GaN-based devices has been studied for a long time, the previous studies mainly focused on Schottky-HFETs<sup>11-29</sup> and MIS-HFETs with oxide gate insulators<sup>4,30-38</sup> with a few exception of a SiN gate insulator.<sup>39</sup> Moreover, in LFN studies for FETs, it is often difficult to identify the contributions from the intrinsic gated and extrinsic ungated parts. Therefore, it is important to obtain insights of LFN in GaN-based MIS-HFETs with nitride insulators such as AlN, comparing with Schottky-HFETs and clarifying the contributions from the intrinsic and extrinsic parts.

In this work, in order to elucidate LFN in AlN/AlGaIn/GaN MIS-HFETs comparing with that in AlGaIn/GaN Schottky-HFETs, we systematically characterized both ungated two-terminal devices and the HFETs. From the characterization, LFN behavior in the intrinsic gated region was extracted for the MIS- and Schottky-HFETs. Although there

is a bias regime of the Schottky HFETs in which LFN is dominated by the gate leakage current, LFN in the MIS-HFETs is always dominated by only the channel current. Analyzing the channel-current-dominated LFN, we obtain Hooge parameters  $\alpha$  for the gated region as a function of the sheet electron concentration under the gate, which exhibits different behaviors for the MIS- and Schottky-HFETs.

## II. DEVICE FABRICATION

Using Al<sub>0.27</sub>Ga<sub>0.73</sub>N(30 nm)/GaN(3000 nm) heterostructure obtained by metal-organic vapor phase epitaxy on sapphire (0001), we fabricated AlN/AlGaIn/GaN MIS devices, i.e., HFETs as well as ungated two-terminal devices. The same sets of AlGaIn/GaN Schottky devices, i.e., HFETs and ungated two-terminal devices, were fabricated simultaneously. The fabrication process is as follows.<sup>7,8</sup> On the AlGaIn/GaN heterostructure, Ti/Al/Ti/Au Ohmic electrodes were formed and device isolation was achieved by B<sup>+</sup> ion implantation. For MIS devices, a 20-nm-thick AlN film as a gate insulator was deposited on the AlGaIn surface by RF magnetron sputtering at room temperature with an AlN target in Ar-N<sub>2</sub> ambient, following the surface treatments, which include oxygen plasma ashing and cleaning by the organic solvents (for removing organic contaminants), and cleaning by Semicoclean (for removing oxides). The formation of Ni/Au gate electrodes on AlN (MIS-HFETs) or AlGaIn (Schottky-HFETs) completed the device fabrication process. The HFETs have gate length  $L_G = 260$  nm, the source-gate spacing of  $2 \mu\text{m}$ , the gate-drain spacing of  $3 \mu\text{m}$ , and the gate width  $W = 50 \mu\text{m}$ . The ungated two-terminal devices have the width  $W = 50, 100 \mu\text{m}$  and electrode spacing of  $L = 2-16 \mu\text{m}$ . Schematics of the devices are shown in Fig. 1.

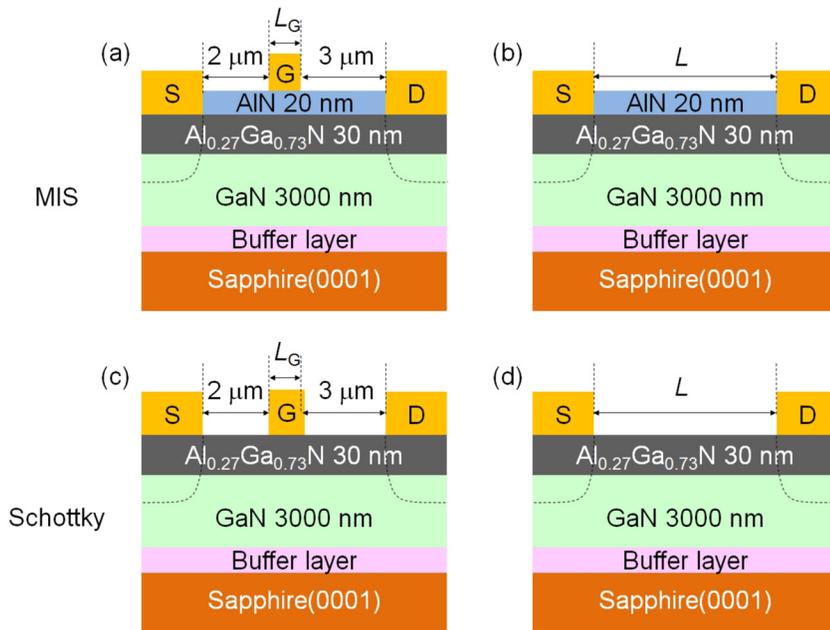

FIG. 1. Schematics of (a) MIS-HFET, (b) MIS ungated two-terminal device, (c) Schottky-HFET, and (d) Schottky ungated two-terminal devices.

### III. DC CHARACTERIZATION OF DEVICES

DC characterization was carried out for the ungated two-terminal devices and the HFETs. From the transfer length method or transmission-line model (TLM) measurements of the ungated devices, we obtain a contact resistance  $r_c = 2.4 \Omega \text{mm}$ , and two-dimensional electron gas (2DEG) sheet resistances of the ungated region  $r_{\text{sug}} = 790$  and  $450 \Omega/\text{sq}$ . for the MIS and Schottky ungated devices, respectively. Hall-effect measurements show the electron mobility of 1200 and  $1500 \text{cm}^2/\text{V-s}$ , and sheet electron concentration of  $n_{\text{sug}} = 6.4 \times 10^{12}$  and  $9.3 \times 10^{12} \text{cm}^{-2}$ , for the MIS and Schottky ungated devices, respectively. Figures 2(a) and 2(b) show output characteristics (normalized by the gate width  $W$ ) of the MIS- and Schottky-HFETs, respectively, where  $I_D$  is the drain current. (Considering LFN characterization, throughout this article, we employ the definition of currents in the unit of [A] without normalization by the device width; the vertical axis of Fig. 2 shows  $I_D/W$  in the unit of [mA/mm].) The Schottky-HFET exhibits negative drain current for large forward gate-source voltages  $V_G$  and small drain-source voltages  $V_D$ , owing to large gate leakage currents. Transfer characteristics (normalized by the gate width  $W$ ) is shown in Fig. 3, where  $I_G$  is the gate current and  $g_m$  is the transconductance: (a) and (b) for the MIS-HFETs, (c) and (d) for the Schottky-HFETs, (a) and (c) for  $V_D = 10 \text{V}$  in the saturation regime, and (b) and (d) for  $V_D = 0.1 \text{V}$  in the linear regime. For the MIS-HFETs, gate currents are significantly small,  $10^{-9} \text{A/mm}$  range or less, about 4 orders for reverse and 8 orders for forward gate biases smaller than those of the Schottky-HFETs, owing to good insulating properties of the AlN. The small gate leakage currents lead to small drain off-currents shown in Figs. 3(a) and 3(b).

### IV. LFN CHARACTERIZATION OF DEVICES

For LFN characterization of the devices, we employed a measurement system consisting of a shielded probe station, a low-noise pre-amplifier (LNA, Stanford SR570), and a

dynamic signal analyzer (DSA, Agilent 35670 A). To measure the ungated two-terminal devices, inside the shielding chamber of the probe station, one Ohmic electrode of the device is

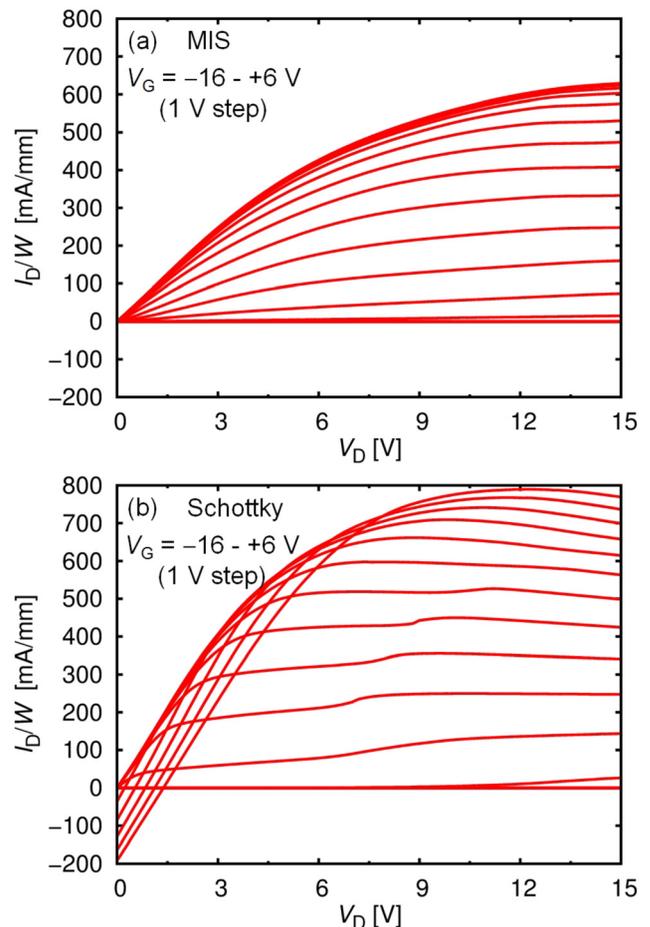

FIG. 2. Output characteristics of (a) MIS- and (b) Schottky-HFETs. Drain current  $I_D$  normalized by the gate width  $W$  as a function of drain-source voltage  $V_D$  is obtained by changing gate-source voltage  $V_G$ .

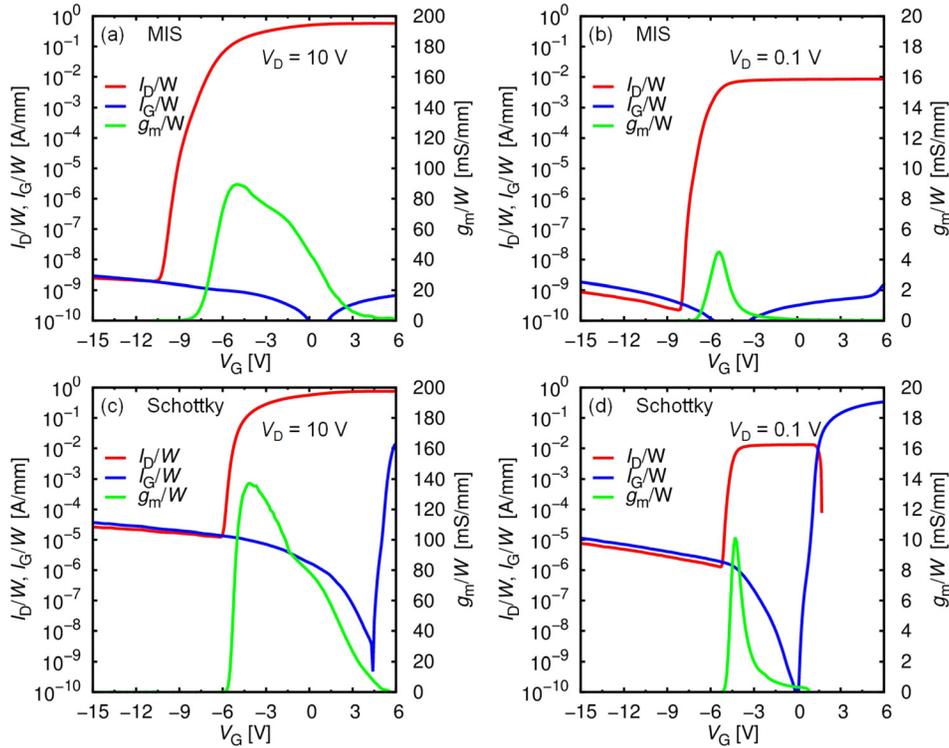

FIG. 3. Transfer characteristics with gate current  $I_G$  and transconductance  $g_m$ : (a) and (b) for MIS-HFETs, (c) and (d) for Schottky-HFETs, (a) and (c) for  $V_D = 10$  V in the saturation regime, and (b) and (d) for  $V_D = 0.1$  V in the linear regime.

connected to the LNA with applications of a DC bias voltage and a DC offset current, while the other Ohmic electrode is grounded. The current noise is amplified by the LNA, whose output is entered to the DSA to obtain the power spectrum density (PSD). For measurements of the HFETs, inside the shielding chamber, the source is grounded, the drain is connected to the LNA with applications of a DC bias drain voltage and a DC offset drain current, and a gate voltage is applied from a parameter analyzer through an RC passive low-pass filter (LPF) with a cut-off frequency  $\sim 0.05$  Hz to eliminate the noise from the parameter analyzer. According to specification of the LPF and the DSA, we obtain the current noise PSD for a frequency range of  $f = 1-10^4$  Hz.

We first measured LFN in the ungated two-terminal devices. Figures 4(a) and 4(b) show examples of measurement results of current noise PSD  $S_I$  for the Ohmic regime of the MIS and Schottky ungated devices, respectively, with  $W = 100 \mu\text{m}$  and  $L = 2, 16 \mu\text{m}$ . We observe  $1/f$  behavior satisfying  $S_I/I^2 \simeq K/f$ , with a constant factor  $K$  depending on the device size, where the DC current  $I$  is varied by changing the bias voltage  $V$ . No specific bump suggests no specific high-density electron traps with a specific time constant. In order to evaluate the factor  $K$ , we plot  $S_I f$  as functions of  $I$  in Figs. 5(a) and 5(b) for the MIS and Schottky ungated devices, respectively, where we can confirm  $S_I f \propto I^2$ .

Since the total resistance of the two-terminal ungated devices is given by  $R = 2R_c + R_{2\text{DEG}}$ , where  $R_c = r_c/W$  from the contact and  $R_{2\text{DEG}} = r_{\text{seg}} L/W$  from the ungated 2DEG, we obtain  $S_I$  of the series-connected resistance

$$S_I = S_I^c \frac{2R_c^2}{(2R_c + R_{2\text{DEG}})^2} + S_I^{2\text{DEG}} \frac{R_{2\text{DEG}}^2}{(2R_c + R_{2\text{DEG}})^2}, \quad (1)$$

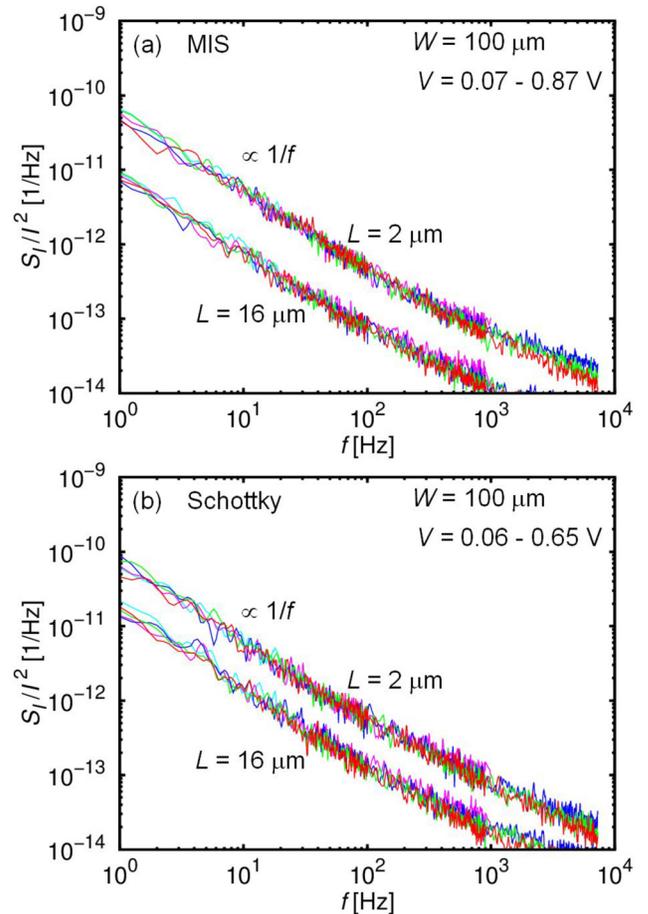

FIG. 4.  $S_I/I^2$  as functions of  $f$  for (a) MIS and (b) Schottky ungated two-terminal devices.

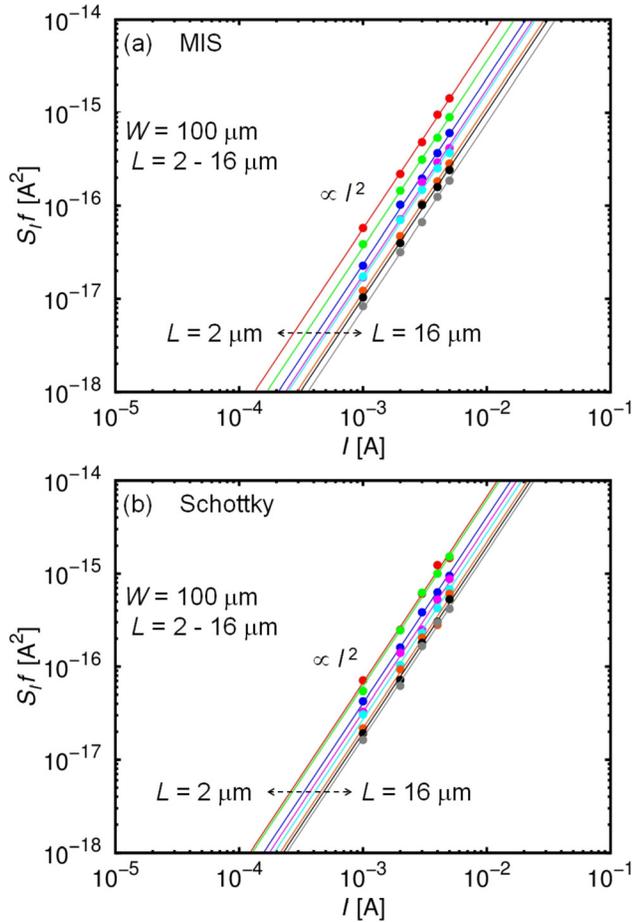

FIG. 5.  $S_I f$  as functions of  $I$  for (a) MIS and (b) Schottky ungated two-terminal devices.

where  $S_I^c$  and  $S_I^{2\text{DEG}}$  are the current noise PSD generated by one contact and the ungated 2DEG, respectively. Hence, we obtain

$$K = \frac{S_I f}{I^2} = K_c \frac{2R_c^2}{(2R_c + R_{2\text{DEG}})^2} + K_{2\text{DEG}} \frac{R_{2\text{DEG}}^2}{(2R_c + R_{2\text{DEG}})^2}, \quad (2)$$

where  $K_c$  and  $K_{2\text{DEG}}$  are the factors for one contact and the ungated 2DEG, respectively. The latter is obtained by the Hooge theory<sup>40</sup>

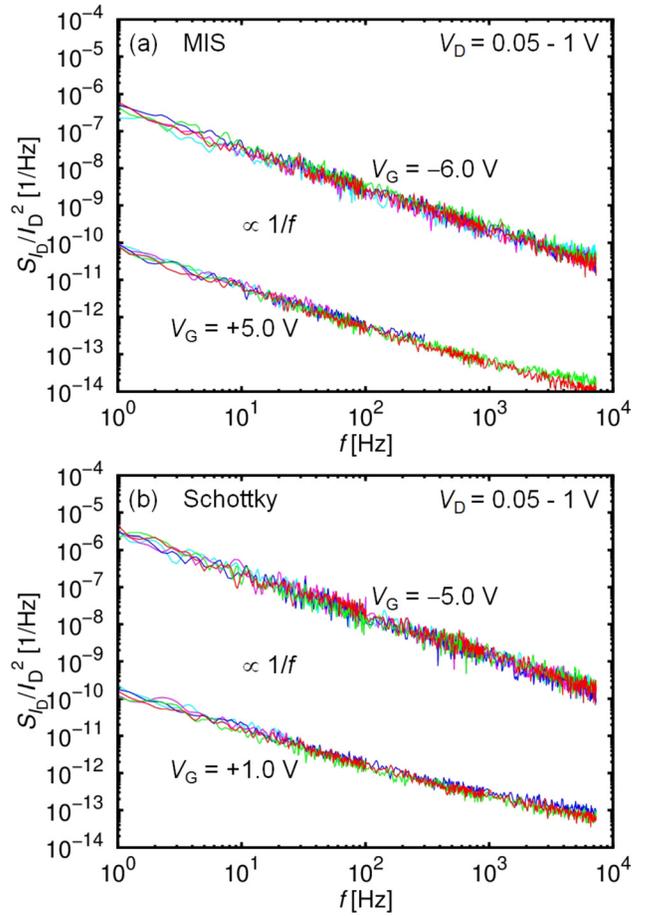

FIG. 7.  $S_I / I_D^2$  as functions of  $f$  for (a) MIS- and (b) Schottky-HFETs.

$$K_{2\text{DEG}} = \frac{\alpha_{\text{ug}}}{N} = \frac{\alpha_{\text{ug}}}{n_{\text{sug}} L W}, \quad (3)$$

where  $\alpha_{\text{ug}}$  is the Hooge parameter and  $N$  is the total electron number of the ungated 2DEG. Since  $R_c \propto 1/W$ ,  $R_{2\text{DEG}} \propto L/W$ ,  $K_c \propto 1/W$ , and  $K_{2\text{DEG}} \propto 1/LW$ ,  $KW$  is a single-valued function of the electrode spacing  $L$  as shown in Fig. 6(a) with the fitting line. Using the relation  $RW = 2r_c + r_{\text{sug}}L$ , we also obtain  $KW$  as a single-valued function of  $RW$  as shown in Fig. 6(b) with the fitting line. From the fitting, we can evaluate  $K_c W \simeq 1.9 \times 10^{-12}$  cm, which is common for the MIS and Schottky devices because of the same Ohmic process. We also obtain  $\alpha_{\text{ug}} \simeq 2.2 \times 10^{-4}$  and

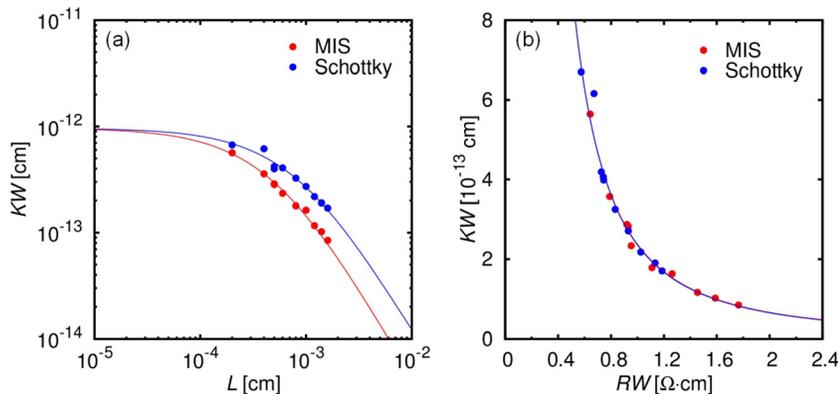

FIG. 6. (a)  $KW$  as a function of the electrode spacing  $L$  and (b) as a function of  $RW$  for MIS and Schottky ungated two-terminal devices.

$5.0 \times 10^{-4}$  for the ungated region of the MIS and Schottky devices, respectively. The smaller Hooge parameter  $\alpha_{\text{ug}}$  in the MIS devices can be attributed to the lower electron mobility due to additional scattering mechanisms caused by the gate insulator deposition, where the mobility fluctuation dominates  $\alpha_{\text{ug}}$  according to the Hooge theory.<sup>40</sup>

We next measured LFN in the HFETs. Figures 7(a) and 7(b) show examples of measurement results of drain current noise PSD  $S_{I_D}$  for the linear regime of the MIS- and Schottky-HFETs, respectively, with the fixed gate voltages  $V_G$ . We also observe  $1/f$  behavior satisfying  $S_{I_D}/I_D^2 \simeq K_{\text{HFET}}/f$  with a factor  $K_{\text{HFET}}$  depending on the fixed  $V_G$ , where the drain current  $I_D$  is varied by changing the drain voltage  $V_D$ . For the purpose of the evaluation of the factor  $K_{\text{HFET}}$ , in Figs. 8(a) and 8(b), we plot  $S_{I_D}f$  as functions of  $I_D$  for the MIS- and Schottky-HFETs, respectively, where we can confirm  $S_{I_D}f \propto I_D^2$ . The factor  $K_{\text{HFET}}$  for the MIS- and Schottky-HFETs as a function of  $V_G$  is plotted in Figs. 9(a) and 9(b), respectively, where the drain current  $I_D$  and the gate current  $I_G$  for  $V_D = 0.1$  V in the linear regime are simultaneously shown. For the Schottky-HFETs, we observe a singular behavior of the factor  $K_{\text{HFET}}$  at  $V_G \simeq -5$  V; in the regime below this voltage, the factor  $K_{\text{HFET}}$  exhibits a weak change. In this regime, the drain current is dominated by the gate leakage as shown in Fig. 9(b). As a result, the LFN is also dominated by the gate leakage, as confirmed by the

relation  $S_{I_D}f \propto I_G^2$  shown in Fig. 9(c). On the other hand, LFN in the MIS-HFETs is always dominated by only the channel current.

For the channel-current-dominated LFN, assuming the HFET on-resistance  $R_{\text{on}}$  given by the series connection of the intrinsic resistance  $R_{\text{int}} = r_s L_G/W$ , where  $r_s$  is the sheet resistance of the gated region, and the extrinsic resistance  $R_{\text{ext}}$  of the ungated part, we also obtain

$$S_{I_D} = S_{I_D}^{\text{int}} \frac{R_{\text{int}}^2}{(R_{\text{int}} + R_{\text{ext}})^2} + S_{I_D}^{\text{ext}} \frac{R_{\text{ext}}^2}{(R_{\text{int}} + R_{\text{ext}})^2} \quad (4)$$

and

$$K_{\text{HFET}} = \frac{S_{I_D}f}{I_D^2} = K_{\text{int}} \frac{R_{\text{int}}^2}{(R_{\text{int}} + R_{\text{ext}})^2} + K_{\text{ext}} \frac{R_{\text{ext}}^2}{(R_{\text{int}} + R_{\text{ext}})^2}, \quad (5)$$

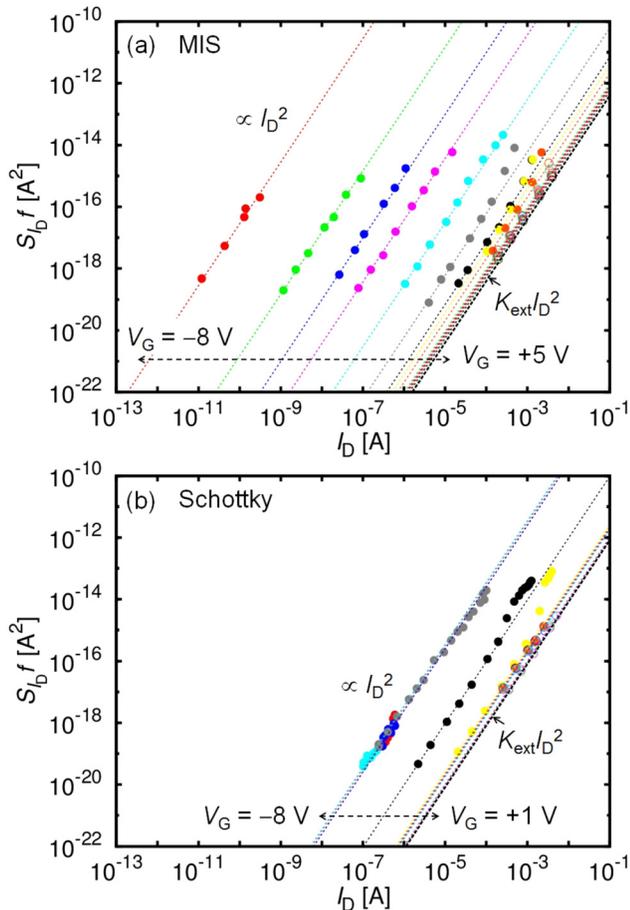

FIG. 8.  $S_{I_D}f$  as functions of  $I_D$  for (a) MIS- and (b) Schottky-HFETs. The line of  $K_{\text{ext}}I_D^2$  is given.

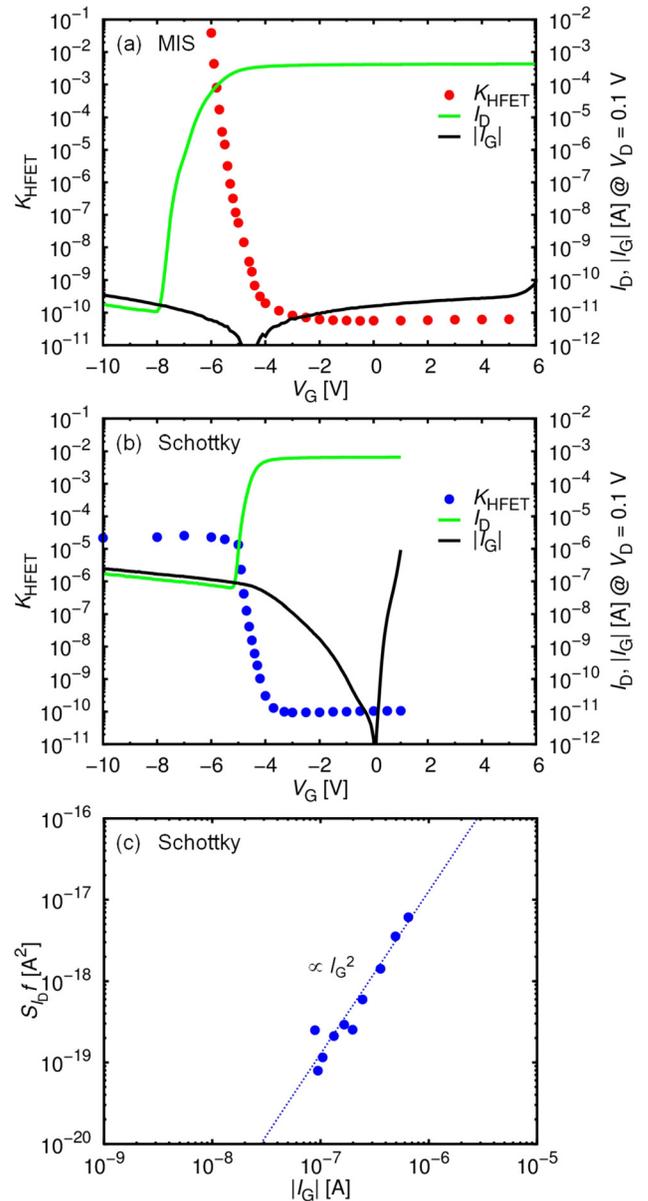

FIG. 9.  $K_{\text{HFET}}$  as a function of  $V_G$  for (a) MIS- and (b) Schottky-HFETs, with  $I_D$  and  $I_G$  in the linear regime. (c)  $S_{I_D}f$  as a function of  $|I_G|$  for Schottky-HFETs.

where  $S_{I_D}^{\text{int}}$  is the PSD generated by the intrinsic gated region with a factor  $K_{\text{int}}$  depending on  $V_G$ , and  $S_{I_D}^{\text{ext}}$  is that by the extrinsic ungated part with a factor  $K_{\text{ext}}$  independent of  $V_G$ . Since the contribution from the ungated part in Eq. (4) is less than  $S_{I_D}^{\text{ext}}$ , when  $S_{I_D} \gg S_{I_D}^{\text{ext}} = K_{\text{ext}} I_D^2 / f$ ,  $S_{I_D}$  is dominated by the intrinsic noise. From the value of the  $R_{\text{ext}}$  obtained by the DC characterization, we can evaluate  $K_{\text{ext}}$  of the ungated part using the relation given in Fig. 6(b);  $K_{\text{ext}} \simeq 4.0 \times 10^{-11}$  and  $8.2 \times 10^{-11}$  for the MIS- and Schottky-HFETs, respectively. In Fig. 8,  $K_{\text{ext}} I_D^2$  is shown by the dotted line; data points approach to the line for large  $V_G$ . Using the value of  $K_{\text{ext}}$ , we can evaluate the contributions to the factor  $K_{\text{HFET}}$  from the first intrinsic and second extrinsic terms in Eq. (5) as shown in Fig. 10, and also obtain  $K_{\text{int}}$  depending on  $V_G$ . In Figs. 11(a) and 11(b), we show the relation between  $K_{\text{int}}$  and the sheet resistance  $r_s$  of the gated region for the MIS- and Schottky-HFETs, respectively. For the small  $r_s$  below the middle of  $10^3 \Omega/\text{sq}$ . range,  $K_{\text{int}} \propto r_s^{-2}$  for both the MIS- and Schottky-HFETs. On the other hand, the MIS-HFETs for  $r_s \geq 10^5 \Omega/\text{sq}$ . exhibit  $K_{\text{int}} \propto r_s^2$ , while the Schottky-HFETs for  $r_s \geq 10^4 \Omega/\text{sq}$ . exhibit  $K_{\text{int}} \propto r_s$ . The  $K_{\text{int}}$  is given by

$$K_{\text{int}} = \frac{\alpha}{N} = \frac{\alpha}{n_s L_G W}, \quad (6)$$

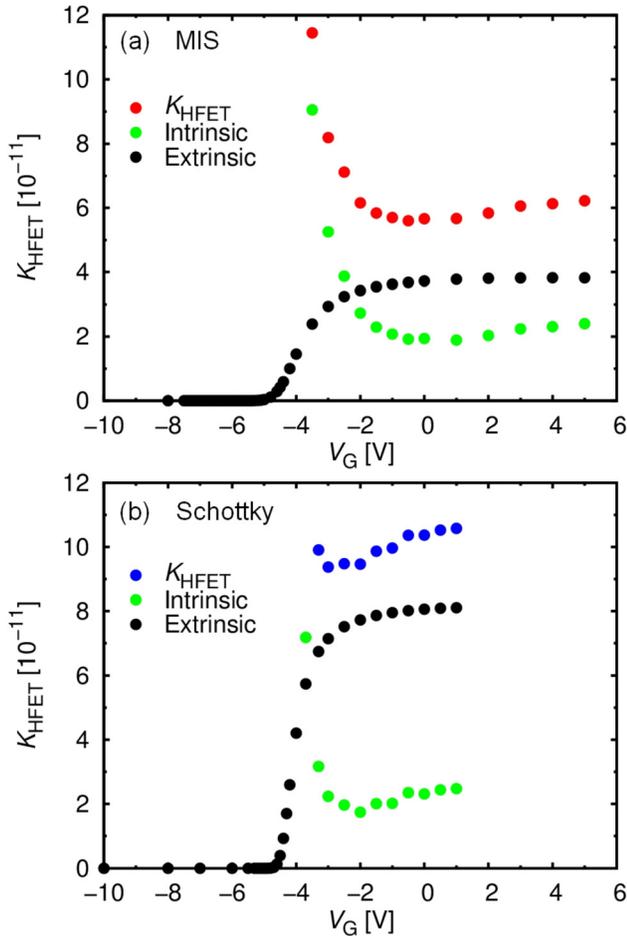

FIG. 10. The intrinsic and extrinsic contributions to  $K_{\text{HFET}}$  for (a) MIS- and (b) Schottky-HFETs.

where  $\alpha$  is the effective Hooge parameter,  $N$  is the total electron number, and  $n_s$  is the sheet electron concentration in the intrinsic gated region. Therefore, in order to obtain  $\alpha$ , it is necessary to evaluate  $n_s$  depending on  $V_G$ . Measuring  $C$ - $V$  characteristics of capacitors simultaneously fabricated, we obtain the capacitance  $C$ , and  $n_s$  calculated from the integration of  $C$ ,<sup>18–20</sup> as shown in Figs. 12(a) and 12(b), for the MIS and Schottky devices, respectively. As a result, we obtain the Hooge parameter  $\alpha$  as a function of  $n_s$  shown in Figs. 13(a) and 13(b) for the MIS- and Schottky-HFETs, respectively. We carried out the same analysis for HFETs with a different gate length  $L_G = 160$  nm, whose results are also given in Fig. 13. The point of  $\alpha_{\text{ug}}$  for the ungated region is simultaneously plotted in Fig. 13. For the MIS-HFETs with the small  $n_s \leq 5 \times 10^{11} \text{ cm}^{-2}$ , with increase in  $n_s$ , we obtain decrease in  $\alpha \propto n_s^{-1}$ . This behavior of  $\alpha \propto n_s^{-1}$  is also observed for the Schottky-HFETs for  $n_s \leq 10^{12} \text{ cm}^{-2}$ . On the other hand, for  $5 \times 10^{11} \text{ cm}^{-2} \leq n_s \leq 1 \times 10^{12} \text{ cm}^{-2}$ , the MIS-HFETs exhibit rapid decrease in  $\alpha$  like  $n_s^{-\xi}$  with  $\xi \sim 2$ -3, which is not observed for the Schottky-HFETs. Moreover, we obtain strong increase in  $\alpha \propto n_s^3$  for  $n_s \geq 2 \times 10^{12} \text{ cm}^{-2}$  for both the MIS- and Schottky-HFETs.

The regime of  $\alpha \propto n_s^{-1}$  corresponds to  $K_{\text{int}} \propto r_s^2$  for the MIS-HFETs and  $K_{\text{int}} \propto r_s$  for the Schottky-HFETs; this difference is caused by different relations between  $n_s$  and the electron mobility  $\mu$  in the intrinsic region. The relation

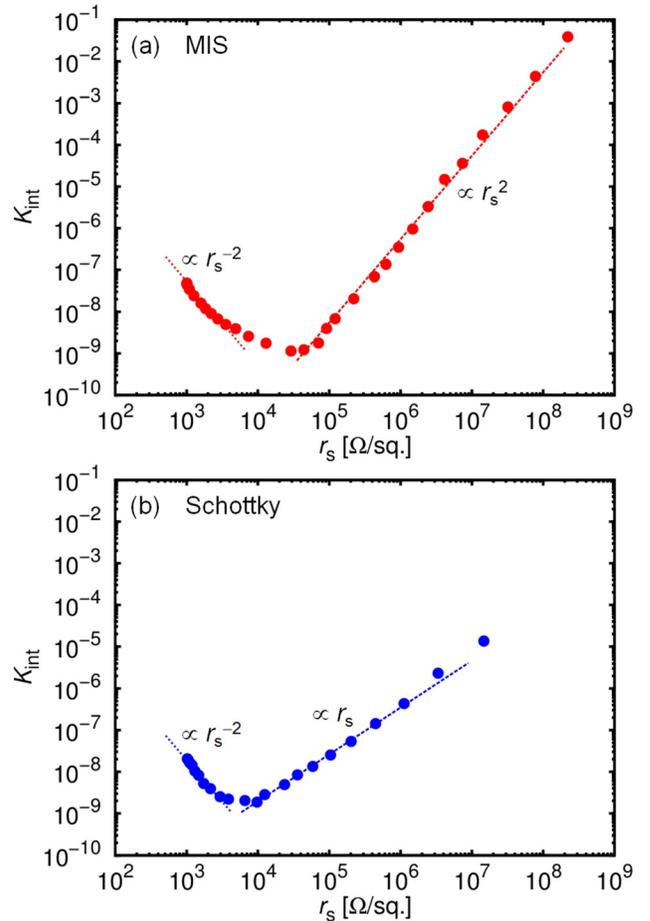

FIG. 11.  $K_{\text{int}}$  as a function of the sheet resistance  $r_s$  of the gated region for (a) MIS- and (b) Schottky-HFETs.

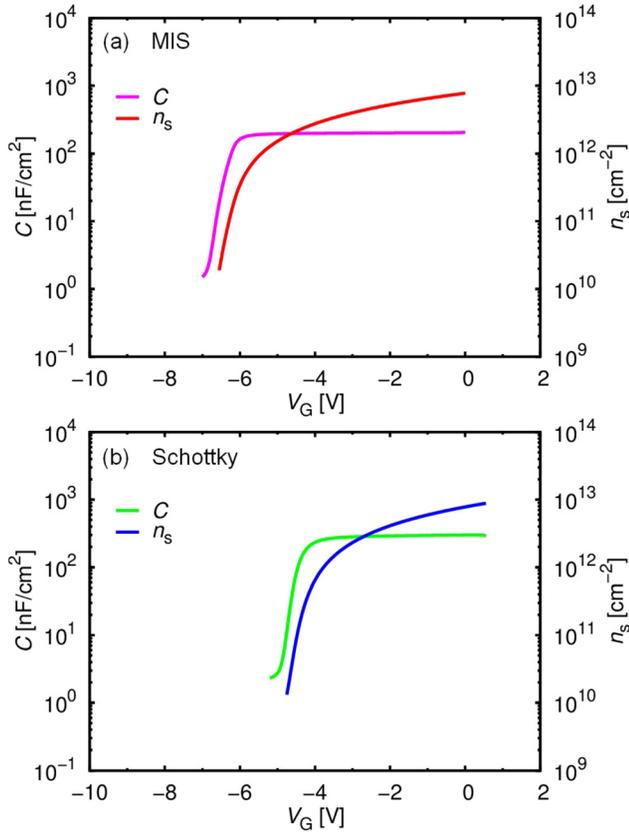

FIG. 12. The capacitance  $C$ , and the sheet electron concentration  $n_s$  under the gate calculated from the integration of  $C$ , as functions of  $V_G$ , for (a) MIS and (b) Schottky devices.

$K_{\text{int}} \propto r_s \propto (n_s \mu)^{-1}$  for the Schottky-HFETs indicates  $\mu \propto n_s$ , while  $K_{\text{int}} \propto r_s^2 \propto (n_s \mu)^{-2}$  for the MIS-HFETs does  $\mu \simeq \text{const.}$  in this regime. This behavior of  $\alpha \propto n_s^{-1}$  is often observed,<sup>17–20,26,41</sup> and can be attributed to the electron number fluctuation due to electron traps in AlGa<sub>N</sub>. In general, according to Burgess theorem,<sup>42</sup> we obtain the current fluctuation

$$\begin{aligned} \frac{(\delta I)^2}{I^2} &= \frac{1}{N} \left[ \frac{(\delta \mu)^2}{\mu^2} + \frac{(\delta N)^2}{N} \right] \\ &\simeq \int_{f_\ell}^{f_h} \frac{S_I}{I^2} df \simeq \int_{f_\ell}^{f_h} \frac{\alpha}{Nf} df = \frac{\alpha}{N} \ln \frac{f_h}{f_\ell}, \end{aligned} \quad (7)$$

where  $f_\ell$  and  $f_h$  are the lower and higher limits of the  $1/f$  spectrum, respectively.<sup>43</sup> This gives

$$\alpha \ln \frac{f_h}{f_\ell} \simeq \frac{(\delta \mu)^2}{\mu^2} + \frac{(\delta N)^2}{N}. \quad (8)$$

The first and second terms correspond to the mobility fluctuation and the electron number fluctuation, respectively. If the electron number fluctuation is dominant, the Hooge parameter is given by

$$\alpha \simeq \frac{(\delta N)^2}{N \ln f_h/f_\ell}. \quad (9)$$

Assuming the electron number fluctuation caused by the traps with a density  $D_0$  (in the unit of [cm<sup>-2</sup>eV<sup>-1</sup>]), we obtain<sup>44</sup>

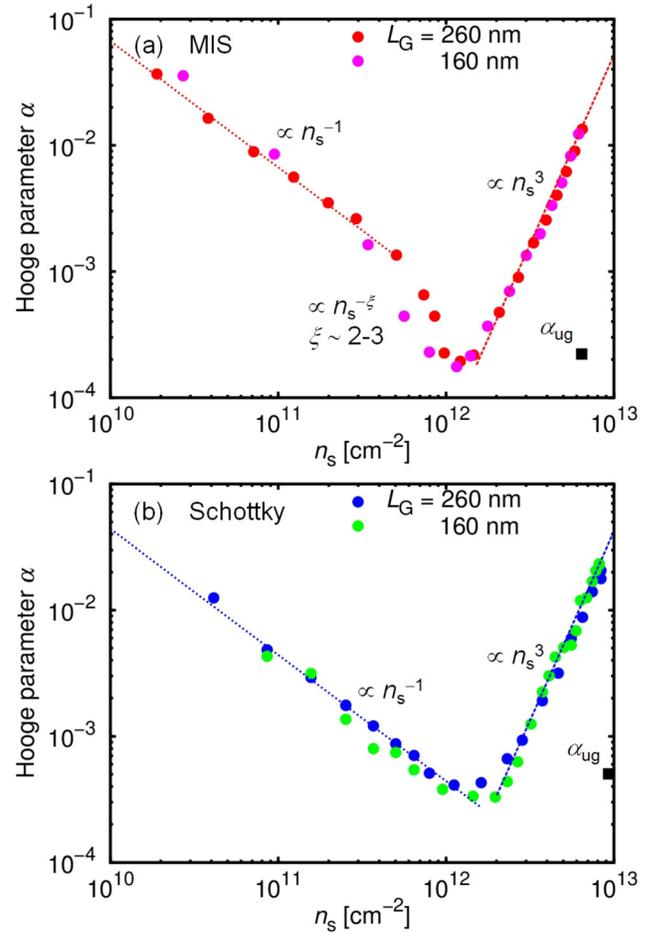

FIG. 13. The Hooge parameter  $\alpha$  as a function of the sheet electron concentration  $n_s$  under the gate for (a) MIS- and (b) Schottky-HFETs.

$$\alpha \sim \frac{D_0 k_B T}{n_s}, \quad (10)$$

which explains the behavior of  $\alpha \propto n_s^{-1}$ . It is natural to consider that this behavior should be significantly influenced by the AlN/AlGa<sub>N</sub> interface states in the MIS-HFETs, whose density is rather high, 10<sup>13</sup> cm<sup>-2</sup>eV<sup>-1</sup> order or more for energy levels near the AlGa<sub>N</sub> conduction band bottom.<sup>7,8</sup> However, the MIS-HFETs and Schottky-HFETs show similar behaviors of  $\alpha \simeq 6.8 \times 10^8 \text{ cm}^{-2} \times n_s^{-1}$  and  $\alpha \simeq 4.4 \times 10^8 \text{ cm}^{-2} \times n_s^{-1}$ , respectively, both giving  $D_0$  of 10<sup>11</sup> cm<sup>-2</sup>eV<sup>-1</sup> order. In this gate bias regime, AlN/AlGa<sub>N</sub> interface state energy levels corresponding to the Fermi energy are deep and have extremely long trapping time constants, for example, calculated to be  $\sim 5 \times 10^3$  s for 0.7 eV below the AlGa<sub>N</sub> conduction band bottom.<sup>8</sup> As a result, trapped electrons at the AlN/AlGa<sub>N</sub> interface states almost “freeze” and, consequently, hardly contribute to the electron number fluctuation. We consider that, for both the MIS- and Schottky-HFETs, the observed  $D_0 \sim 10^{11} \text{ cm}^{-2} \text{ eV}^{-1}$  is reasonable for traps in AlGa<sub>N</sub> close to the AlGa<sub>N</sub>/Ga<sub>N</sub> interface, which have much shorter time constants. On the other hand, the rapid decrease in  $\alpha$  like  $n_s^{-\xi}$  with  $\xi \sim 2-3$  is observed only for the MIS-HFET. We tentatively assume that this behavior is attributed to the mobility fluctuation specific for the MIS-HFETs. In addition, for both the MIS- and

Schottky-HFETs, we observe the strong increase in  $\alpha \propto n_s^3$  for large  $n_s$ . This corresponds to  $K_{\text{int}} \propto r_s^{-2}$ , indicating  $\mu \simeq \text{const}$ . Such increase was observed for Schottky-HFETs with large  $V_G$  (Refs. 18–20) and sometimes attributed to large gate leakage currents. However, this behavior cannot be attributed to the gate leakage, which is significantly suppressed in the MIS-HFETs, but can be related to the fluctuation in the intrinsic gate voltage, which is enhanced for large  $V_G$  and  $n_s$  by the fluctuation of the voltage across the extrinsic source resistance. According to this,  $\alpha$  of the gated region is larger than  $\alpha_{\text{ug}}$  of the ungated region for the same sheet electron concentration, as confirmed in Fig. 13. Even for the intrinsic gated region, the LFN can be influenced by the extrinsic part through the fluctuation of the intrinsic gate voltage.

## V. CONCLUSION

We have systematically investigated LFN in AlN/AlGaIn/GaN MIS devices in comparison with that in AlGaIn/GaN Schottky devices. By measuring LFN in ungated two-terminal devices and HFETs, we elucidated LFN characteristics in the intrinsic gated region of the HFETs. Although there is a bias regime of the Schottky HFETs in which LFN is dominated by the gate leakage current, LFN in the MIS-HFETs is always dominated by only the channel current. Analyzing the channel-current-dominated LFN, we obtained Hooge parameters for the gated region as a function of the sheet electron concentration under the gate, which exhibits different behaviors for the MIS- and Schottky-HFETs.
