(Received 29 November 2017; accepted 3 January 2018; published online 19 January 2018)

We have investigated insulator-semiconductor interface fixed charges in AlGaIn/GaN metal-insulator-semiconductor (MIS) devices with Al<sub>2</sub>O<sub>3</sub> or AlTiO (an alloy of Al<sub>2</sub>O<sub>3</sub> and TiO<sub>2</sub>) gate dielectrics obtained by atomic layer deposition on AlGaIn. Analyzing insulator-thickness dependences of threshold voltages for the MIS devices, we evaluated positive interface fixed charges, whose density at the AlTiO/AlGaIn interface is significantly lower than that at the Al<sub>2</sub>O<sub>3</sub>/AlGaIn interface. This and a higher dielectric constant of AlTiO lead to rather shallower threshold voltages for the AlTiO gate dielectric than for Al<sub>2</sub>O<sub>3</sub>. The lower interface fixed charge density also leads to the fact that the two-dimensional electron concentration is a decreasing function of the insulator thickness for AlTiO, whereas being an increasing function for Al<sub>2</sub>O<sub>3</sub>. Moreover, we discuss the relationship between the interface fixed charges and interface states. From the conductance method, it is shown that the interface state densities are very similar at the Al<sub>2</sub>O<sub>3</sub>/AlGaIn and AlTiO/AlGaIn interfaces. Therefore, we consider that the lower AlTiO/AlGaIn interface fixed charge density is not owing to electrons trapped at deep interface states compensating the positive fixed charges and can be attributed to a lower density of oxygen-related interface donors.

## I. INTRODUCTION

GaN-based heterojunction field-effect transistors (HFETs)<sup>1</sup> are important devices owing to their high current drive capability and high breakdown voltages. However, there are several disadvantages of GaN-based HFETs; self-heating effects,<sup>2-4</sup> current collapse phenomena,<sup>5,6</sup> and also gate leakage currents are limiting factors for the practical use of these devices. For the suppression of gate leakage currents and the current collapse phenomena in GaN-based devices, it can be effective to employ metal-insulator-semiconductor (MIS) structures, which are also significant to normally off operations,<sup>7</sup> even though GaN-based MIS devices sometimes exhibit unstable characteristics.<sup>8-12</sup> As a gate dielectric of GaN-based MIS devices, high-dielectric-constant (high- $k$ ) insulators, such as Al<sub>2</sub>O<sub>3</sub>,<sup>13</sup> HfO<sub>2</sub>,<sup>14,15</sup> TaON,<sup>16</sup> AlN,<sup>17-21</sup> BN,<sup>22,23</sup> and AlTiO,<sup>24</sup> have been investigated. In GaN-based MIS device processing, when an insulator is deposited on a negatively polarized III-N semiconductor surface, such as Ga-face (Al)GaN, positive insulator-semiconductor interface fixed charges tend to be generated and to cancel the negative polarization charges.<sup>25-32</sup> However, the existence of the insulator-semiconductor interface fixed charges is not a necessity.<sup>29,30</sup> Since the interface fixed charges have significant impacts on threshold voltages  $V_{th}$ , we expect that  $V_{th}$  can be controlled by “interface charge engineering,”<sup>29</sup> i.e., by controlling the interface fixed charges. In particular, if the positive interface fixed charge density is sufficiently suppressed, a normally off operation can be expected.<sup>33,34</sup>

However, despite many reports on the interface fixed charges, their sufficient control is a remaining issue. Moreover, their origin is not fully elucidated even though they are attributed to positively ionized oxygen donors in some cases. Therefore, further investigations on insulator-semiconductor interface fixed charges for GaN-based MIS devices are very necessary and important towards  $V_{th}$  control and normally off operations.

In this work, we investigated insulator-semiconductor interface fixed charges in AlGaIn/GaN MIS devices with Al<sub>2</sub>O<sub>3</sub> or AlTiO (an alloy of Al<sub>2</sub>O<sub>3</sub> and TiO<sub>2</sub><sup>35-37</sup>) gate dielectrics, which are deposited on an AlGaIn/GaN heterostructure by atomic layer deposition (ALD). AlTiO has, depending on its composition, intermediate physical properties between Al<sub>2</sub>O<sub>3</sub> ( $k \sim 9$  and  $E_g \sim 7$  eV) and TiO<sub>2</sub> ( $k \sim 60$  and  $E_g \sim 3$  eV),<sup>37</sup> being useful to balance the trade-off between  $k$  and energy gap  $E_g$ . Previously, we fabricated AlTiO/AlGaIn/GaN MIS devices with excellent characteristics, indicating that AlTiO can be an important candidate for a gate dielectric of GaN-based MIS devices.<sup>24</sup> The present work involves a comparative study on insulator-semiconductor interface fixed charges in Al<sub>2</sub>O<sub>3</sub>/AlGaIn/GaN and AlTiO/AlGaIn/GaN MIS devices. By analyzing linear insulator-thickness dependences of  $V_{th}$ , we evaluated insulator-semiconductor interface fixed charges. As a result, we find that the fixed charge density at the AlTiO/AlGaIn interface is significantly lower than that at the Al<sub>2</sub>O<sub>3</sub>/AlGaIn interface. In addition, we also discuss the relationship between the interface fixed charges and interface states. It is suggested that the lower AlTiO/AlGaIn interface fixed charge density is not owing to electrons trapped at deep interface states.

## II. DEVICE FABRICATION

Using an  $\text{Al}_{0.27}\text{Ga}_{0.73}\text{N}$  (30 nm)/GaN (3000 nm) heterostructure grown by metal-organic vapor phase epitaxy on sapphire(0001), we fabricated AlGaN/GaN MIS devices with  $\text{Al}_2\text{O}_3$  or AlTiO gate dielectrics. The device fabrication was started with Ti/Al/Ti/Au Ohmic electrode formation. After surface treatments using organic solvents, oxygen plasma ashing, and an ammonium-based solution, insulator films of  $\text{Al}_2\text{O}_3$  or AlTiO as gate dielectrics with several thicknesses  $d_{\text{ins}} = 6\text{--}29\text{ nm}$  were deposited on the AlGaN surface by ALD. The  $\text{Al}_2\text{O}_3$  films ( $k \sim 9$  and  $E_g \sim 7\text{ eV}$ ) were obtained by using trimethylaluminum (TMA) and  $\text{H}_2\text{O}$  as precursors, and the  $\text{Al}_x\text{Ti}_y\text{O}$  films ( $x:y = 0.73:0.27$ ,  $k \sim 13\text{--}14$ , and  $E_g \sim 6\text{ eV}$ ) were by using TMA, tetrakis-dimethylamino titanium (TDMAT), and  $\text{H}_2\text{O}$ . After post-deposition annealing in  $\text{H}_2$ -mixed Ar at  $350^\circ\text{C}$ , Ni/Au gate electrode formation completed the device fabrication. As a result, we obtained  $\text{Al}_2\text{O}_3/\text{AlGaN}/\text{GaN}$  and AlTiO/AlGaN/GaN MIS devices, whose cross sections are schematically shown in Fig. 1(a), with  $70\ \mu\text{m} \times 70\ \mu\text{m}$  gate electrodes surrounded by the Ohmic electrodes as shown by top-view optical images in Fig. 1(b).

## III. INSULATOR-SEMICONDUCTOR INTERFACE FIXED CHARGES

In order to investigate insulator-semiconductor interface fixed charges, we examined threshold voltages  $V_{\text{th}}$  of the  $\text{Al}_2\text{O}_3/\text{AlGaN}/\text{GaN}$  and AlTiO/AlGaN/GaN MIS devices, by measuring capacitance-voltage ( $C$ - $V$ ) characteristics between the gate and the grounded Ohmic electrodes. Since GaN-based MIS devices sometimes exhibit unstable  $V_{\text{th}}$  depending on the sweeping range of the gate voltage  $V_G$ ,<sup>8–12</sup> we checked  $V_{\text{th}}$  stability; starting from  $V_{G0} \geq 0$ ,  $C$ - $V$  characteristics were measured under  $V_G = V_{G0} \rightarrow -15\text{ V}$  with a sweep rate of  $0.36\text{ V/s}$ . Figure 2 shows an example of the

FIG. 1. (a) Schematic cross sections and (b) top-view optical images of the fabricated  $\text{Al}_2\text{O}_3/\text{AlGaN}/\text{GaN}$  and AlTiO/AlGaN/GaN MIS devices.

FIG. 2. Checking  $V_{\text{th}}$  stability of the  $\text{Al}_2\text{O}_3/\text{AlGaN}/\text{GaN}$  and AlTiO/AlGaN/GaN MIS devices with  $d_{\text{ins}} = 19\text{ nm}$ :  $C$ - $V$  characteristics measured at  $1\text{ MHz}$  under  $V_G = V_{G0} \rightarrow -15\text{ V}$  with a sweep rate of  $0.36\text{ V/s}$ , where  $V_{G0} = 0, 1, 2, 3, 4,$  and  $5\text{ V}$ .

measurement results for  $d_{\text{ins}} = 19\text{ nm}$ , at  $1\text{ MHz}$  frequency with  $V_{G0} = 0, 1, 2, 3, 4,$  and  $5\text{ V}$ . Although we find rather stable  $V_{\text{th}}$ , weak  $V_{\text{th}}$  shifts take place after positive bias applications, probably owing to charging effects of trapped electrons. Thus, to determine  $V_{\text{th}}$ , we employ  $V_{G0} = 0\text{ V}$  to avoid the charging effects. Figure 3(a) shows  $C$ - $V$  characteristics of the MIS devices with  $d_{\text{ins}} = 6\text{--}29\text{ nm}$ , measured at  $1\text{ MHz}$  under  $V_G = 0 \rightarrow -15\text{ V}$  with a sweep rate of  $0.36\text{ V/s}$ . As shown in Fig. 3(b), the sheet concentration of the two-dimensional electron gas (2DEG) under the gate,  $n_s$ , can be obtained by integrating  $C$  as a function of  $V_G$ , from which we can determine  $V_{\text{th}}$ .

Figure 4 shows the band diagram of AlGaN/GaN MIS devices, considering the interface fixed charges. From this, we obtain

$$\frac{\Delta\sigma_{\text{ins}} - qn_s}{k_{\text{ins}}\epsilon_0}d_{\text{ins}} + \frac{\Delta\sigma_{\text{AlGaN}} - qn_s}{k_{\text{AlGaN}}\epsilon_0}d_{\text{AlGaN}} = -V_G + \psi/q + E_F/q \quad (1)$$

using the elementary charge  $q > 0$ , the vacuum permittivity  $\epsilon_0$ , the insulator-semiconductor interface fixed charge density  $\sigma_{\text{ins}}$ , the polarization charge densities  $\sigma_{\text{GaN}}$  and  $\sigma_{\text{AlGaN}}$ , the dielectric constants  $k_{\text{ins}}$  and  $k_{\text{AlGaN}}$ , the thicknesses  $d_{\text{ins}}$  and  $d_{\text{AlGaN}}$ , the 2DEG Fermi energy  $E_F$ , and  $\psi = \phi - \phi - \Delta E_C$  defined in Fig. 4, where  $\Delta\sigma_{\text{ins}} = \sigma_{\text{ins}} - \sigma_{\text{GaN}}$  and  $\Delta\sigma_{\text{AlGaN}} = \sigma_{\text{AlGaN}} - \sigma_{\text{GaN}}$ . For  $V_G = V_{\text{th}}$  ( $n_s = 0$  and  $E_F = 0$ ), we find

$$V_{\text{th}} = -\frac{\Delta\sigma_{\text{ins}}}{k_{\text{ins}}\epsilon_0}d_{\text{ins}} - \frac{\Delta\sigma_{\text{AlGaN}}}{k_{\text{AlGaN}}\epsilon_0}d_{\text{AlGaN}} + \psi/q \quad (2)$$

giving a linear  $d_{\text{ins}}$ -dependence of  $V_{\text{th}}$  with a slope of  $-\Delta\sigma_{\text{ins}}/(k_{\text{ins}}\epsilon_0)$ . The 2DEG concentration  $n_s$  under the gate is approximately given by

$$qn_s \simeq C_0(V_G - V_{\text{th}}) \quad (3)$$

as experimentally confirmed in Fig. 3(b), where

$$\frac{1}{C_0} = \frac{d_{\text{ins}}}{k_{\text{ins}}\epsilon_0} + \frac{d_{\text{AlGaN}}}{k_{\text{AlGaN}}\epsilon_0}. \quad (4)$$

FIG. 3. (a)  $C$ - $V$  characteristics of the  $\text{Al}_2\text{O}_3/\text{AlGaIn}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaIn}/\text{GaN}$  MIS devices with  $d_{\text{ins}}=6$ – $29$  nm, measured at 1 MHz under  $V_G=0 \rightarrow -15$  V with a sweep rate of 0.36 V/s. (b) The 2DEG sheet concentration  $n_s$  obtained by integrating  $C$  as functions of the gate voltage  $V_G$ , from which we can determine  $V_{\text{th}}$ .

FIG. 4. The band diagram of  $\text{AlGaIn}/\text{GaN}$  MIS devices, considering the interface fixed charges.

For  $V_G=0$ ,  $n_s = n_{s0}$  is given by

$$qn_{s0} \simeq -C_0 V_{\text{th}} = \frac{\Delta\sigma_{\text{ins}}d_{\text{ins}}/(k_{\text{ins}}\epsilon_0) + \Delta\sigma_{\text{AlGaIn}}d_{\text{AlGaIn}}/(k_{\text{AlGaIn}}\epsilon_0) - \psi/q}{d_{\text{ins}}/(k_{\text{ins}}\epsilon_0) + d_{\text{AlGaIn}}/(k_{\text{AlGaIn}}\epsilon_0)} \quad (5)$$

which is a nonlinear function of  $d_{\text{ins}}$ .

According to Eq. (4),  $1/C_0$  is a linear function of  $d_{\text{ins}}$ . Experimentally,  $C_0$  is estimated by  $C$  at  $V_G=0$  V as plotted in Fig. 5(a), where we can confirm the linear relation. From the slopes, we obtain dielectric constants  $k_{\text{ins}}=9.4$  and  $13.4$  for  $\text{Al}_2\text{O}_3$  and  $\text{AlTiO}$ , respectively, being consistent with separated experimental results using metal-insulator-metal structures (not shown). From the intercept, we obtain  $k_{\text{AlGaIn}}=9.5$  (using  $d_{\text{AlGaIn}}=30$  nm). Figure 5(b) shows the experimentally determined  $V_{\text{th}}$  as functions of  $d_{\text{ins}}$ . We find linear dependences obeying Eq. (2), indicating that the interface fixed charges dominate  $V_{\text{th}}$  and also rather shallower  $V_{\text{th}}$  for  $\text{AlTiO}$  than for  $\text{Al}_2\text{O}_3$ . By fitting using Eq. (2), we obtain  $\Delta\sigma_{\text{ins}}/q = 1.5 \times 10^{13} \text{ cm}^{-2}$  and  $7.3 \times 10^{12} \text{ cm}^{-2}$  at the  $\text{Al}_2\text{O}_3/\text{AlGaIn}$  and  $\text{AlTiO}/\text{AlGaIn}$  interfaces, respectively. The latter gives a significantly lower  $\sigma_{\text{ins}}$  than the former, which may be attributed to a lower-density of oxygen donors<sup>25,31,32</sup> at

FIG. 5. (a)  $1/C_0$ , (b)  $V_{\text{th}}$ , and (c)  $n_{s0}$  at  $V_G = 0$  of the  $\text{Al}_2\text{O}_3/\text{AlGaN}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaN}/\text{GaN}$  MIS devices, as functions  $d_{\text{ins}}$  with fitting curves.

the  $\text{AlTiO}/\text{AlGaN}$  interface. This lower  $\sigma_{\text{ins}}$  and the higher  $k_{\text{ins}}$  of  $\text{AlTiO}$  lead to rather shallower  $V_{\text{th}}$ . Figure 5(c) shows the experimentally obtained  $n_{s0}$  as functions of  $d_{\text{ins}}$ , whose non-linear dependences are fitted by Eq. (5). We find that  $n_{s0}$  is a decreasing function of  $d_{\text{ins}}$  for  $\text{AlTiO}$ , whereas being an increasing function for  $\text{Al}_2\text{O}_3$ . From Eq. (5), we obtain

$$\frac{\partial n_{s0}}{\partial d_{\text{ins}}} = \frac{C_0}{k_{\text{ins}} \epsilon_0} (\Delta\sigma_{\text{ins}}/q - n_{s0}) \quad (6)$$

which implies that  $\Delta\sigma_{\text{ins}}/q > n_{s0}$  leads to increasing  $n_{s0}$  with  $d_{\text{ins}}$ , while  $\Delta\sigma_{\text{ins}}/q < n_{s0}$  leads to decreasing  $n_{s0}$ . Thus, for  $\text{Al}_2\text{O}_3$  and  $\text{AlTiO}$ ,  $n_{s0}$  is an increasing and a decreasing function of  $d_{\text{ins}}$ , respectively. It should be noted that, in the limit

of a large  $d_{\text{ins}}$ ,  $n_{s0}$  in Eq. (5) approaches to  $\Delta\sigma_{\text{ins}}/q$ , indicating that a normally off operation can be expected for sufficiently suppressed interface fixed charges, satisfying  $\Delta\sigma_{\text{ins}} < 0$ , i.e.,  $\sigma_{\text{ins}} < \sigma_{\text{GaN}}$ . However, in the both cases, we observe  $\Delta\sigma_{\text{ins}} > 0$ , i.e.,  $\sigma_{\text{ins}} > \sigma_{\text{GaN}}$ .

Even though  $\Delta\sigma_{\text{ins}}$  is obtained experimentally, in order to evaluate  $\sigma_{\text{ins}}$ , it is necessary to assume  $\sigma_{\text{GaN}}$ . Hereafter, we assume  $\sigma_{\text{GaN}}/q = 2.1 \times 10^{13} \text{ cm}^{-2}$  obtained by a theoretical calculation.<sup>38</sup> This leads to  $\sigma_{\text{ins}}/q = 3.6 \times 10^{13} \text{ cm}^{-2}$  and  $2.8 \times 10^{13} \text{ cm}^{-2}$  at the  $\text{Al}_2\text{O}_3/\text{AlGaN}$  and  $\text{AlTiO}/\text{AlGaN}$  interfaces, respectively. In addition, these values should be compared with  $\sigma_{\text{AlGaN}}/q$ . Although  $\Delta\sigma_{\text{AlGaN}}/q = 1.5 \times 10^{13} \text{ cm}^{-2}$  for  $\text{Al}_{0.27}\text{Ga}_{0.73}\text{N}/\text{GaN}$  is obtained theoretically,<sup>39</sup> several experiments show lower  $\Delta\sigma_{\text{AlGaN}}$ , about 85% of the theoretical one.<sup>40–42</sup> Thus, we assume  $\Delta\sigma_{\text{AlGaN}}/q = 1.3 \times 10^{13} \text{ cm}^{-2}$ , i.e.,  $\sigma_{\text{AlGaN}}/q = 3.4 \times 10^{13} \text{ cm}^{-2}$ . Based on the assumptions, we summarize  $\sigma_{\text{ins}}$  compared with  $\sigma_{\text{AlGaN}}$  in Fig. 6, where the dotted line corresponds to neutral insulator-semiconductor interfaces, i.e.,  $\sigma_{\text{ins}} + (-\sigma_{\text{AlGaN}}) = 0$ . We obtain that the  $\text{Al}_2\text{O}_3/\text{AlGaN}$  interface is nearly neutral,<sup>25</sup> while the  $\text{AlTiO}/\text{AlGaN}$  interface is rather negatively charged owing to the lower  $\sigma_{\text{ins}}$ . By fitting  $V_{\text{th}}$  as functions of  $d_{\text{ins}}$  with Eq. (2), we also obtain  $\psi = 2.0$  and  $1.3 \text{ eV}$  for the  $\text{Al}_2\text{O}_3/\text{AlGaN}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaN}/\text{GaN}$  MIS devices, respectively. From these, we obtain band diagrams of the  $\text{AlGaN}/\text{GaN}$  MIS devices by Poisson-Schrödinger calculation<sup>43</sup> as shown in Fig. 7, where we can confirm that the  $\text{AlTiO}/\text{AlGaN}$  interface is negatively charged. The directions of the electric fields in  $\text{Al}_2\text{O}_3$  and  $\text{AlTiO}$  at  $V_G = 0 \text{ V}$  are opposite, leading to the fact that  $n_{s0}$  is a decreasing function of  $d_{\text{ins}}$  for  $\text{AlTiO}$ , whereas being an increasing function for  $\text{Al}_2\text{O}_3$ .

#### IV. RELATION WITH INSULATOR-SEMICONDUCTOR INTERFACE STATES

It should be noted that electrons trapped at deep interface states with very long time constants can act as (quasi) negative interface fixed charges.<sup>30</sup> Therefore, the interface fixed charge measurements might be influenced by electrons at deep interface states compensating the positive fixed

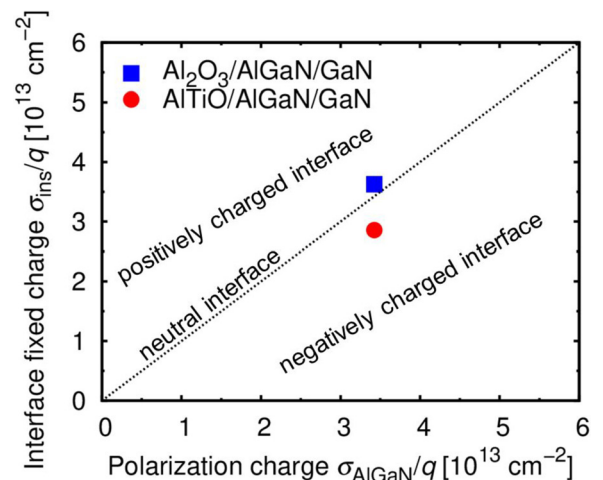

FIG. 6. A comparison between the insulator-semiconductor interface fixed charge density  $\sigma_{\text{ins}}$  and  $\text{AlGaN}$  polarization charge density  $\sigma_{\text{AlGaN}}$ .

FIG. 7. Band diagrams of the  $\text{Al}_2\text{O}_3/\text{AlGaIn}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaIn}/\text{GaN}$  MIS devices at  $V_G = 0$  V, obtained by 1D Poisson-Schrödinger calculation.

charges. In particular, there is a possibility that the lower  $\text{AlTiO}/\text{AlGaIn}$  interface fixed charge density is owing to electrons trapped at deep interface states. In order to consider this possibility, we examined the interface states at  $\text{Al}_2\text{O}_3/\text{AlGaIn}$  and  $\text{AlTiO}/\text{AlGaIn}$  by frequency dependent  $C$ - $V$  measurements. Figure 8 shows examples of the measurement results,  $C$ - $V$  characteristics at 100 Hz–1 MHz for the  $\text{Al}_2\text{O}_3/\text{AlGaIn}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaIn}/\text{GaN}$  MIS devices with  $d_{\text{ins}} = 14$ – $19$  nm. In any cases, no frequency dispersion is observed for negative bias voltages, showing that the  $V_{\text{th}}$  determination is not affected by the measurement frequency. On the other hand, for positive bias voltages, frequency dispersions are observed, suggesting insulator-semiconductor interface states.

The conductance method<sup>44</sup> was applied to the frequency dependent  $C$ - $V$  characteristics to evaluate the interface state density.<sup>30,45–51</sup> Assuming the equivalent circuit shown in the insets of Fig. 9, which consists of an interface state capacitance  $C_i$ , an interface state conductance  $G_i$ , and an  $\text{AlGaIn}$  capacitance  $C_{\text{AlGaIn}}$  in parallel, with an insulator capacitance  $C_{\text{ins}}$  connected in series, we obtained the frequency dependence of  $G_i$  for the  $\text{Al}_2\text{O}_3/\text{AlGaIn}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaIn}/\text{GaN}$  MIS devices. Figure 9 shows examples of obtained  $G_i/\omega$  as functions of frequency  $f$ , where  $\omega = 2\pi f$ , exhibiting single-peaked behavior. As shown by the curves in Fig. 9, the single-peaked behavior is well fitted by<sup>52</sup>

$$\frac{G_i}{\omega} = \frac{q^2 D_i \ln(1 + \omega^2 \tau^2)}{2\omega\tau}, \quad (7)$$

where  $D_i$  is the interface state density and  $\tau$  is the trapping time constant, giving the peak frequency  $f_p = 1/(\pi\tau)$  and the peak value of  $G_i/\omega \simeq 0.4q^2 D_i$ . The observed peaks are summarized in Fig. 10(a), where we find very similar behavior

FIG. 8.  $C$ - $V$  characteristics of the  $\text{Al}_2\text{O}_3/\text{AlGaIn}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaIn}/\text{GaN}$  MIS devices with  $d_{\text{ins}} = 14$ – $19$  nm, measured at 100 Hz–1 MHz.

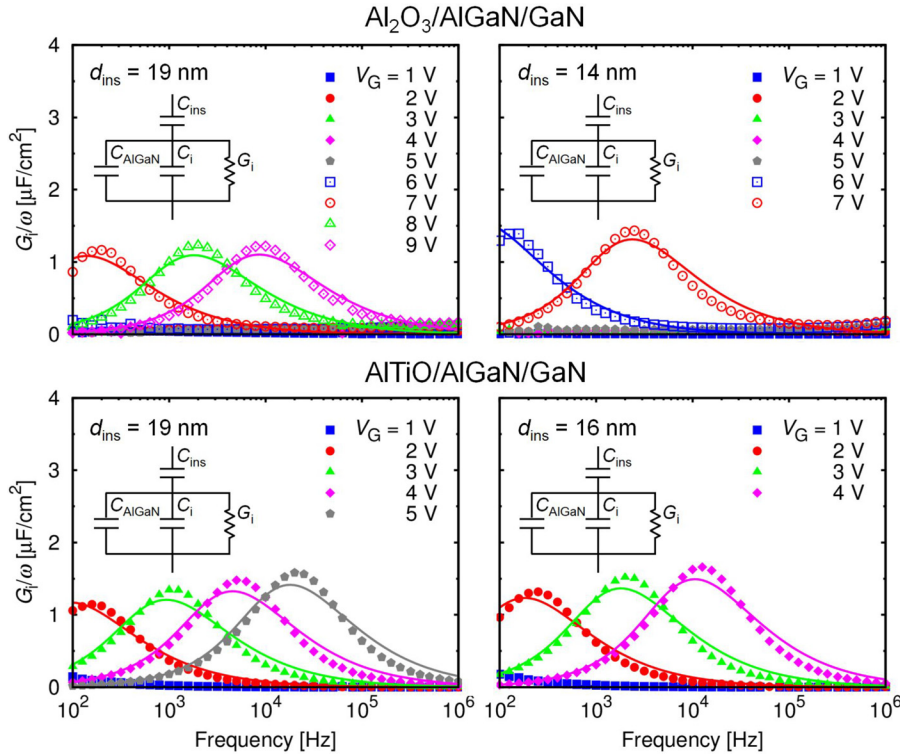

FIG. 9.  $G_i/\omega$  as functions of frequency with fitting curves for the  $\text{Al}_2\text{O}_3/\text{AlGaIn}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaIn}/\text{GaN}$  MIS devices. Insets: The small-signal equivalent circuit.

FIG. 10. (a) The peak value of  $G_i/\omega$  as functions of peak frequency  $f_p$  and (b) the interface state density  $D_i$  as functions of the energy  $(E_C - E)$ , for the  $\text{Al}_2\text{O}_3/\text{AlGaIn}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaIn}/\text{GaN}$  MIS devices.

for  $\text{Al}_2\text{O}_3/\text{AlGaIn}/\text{GaN}$  and  $\text{AlTiO}/\text{AlGaIn}/\text{GaN}$  and also for different  $d_{\text{ins}}$ , suggesting that the behavior is dominated by interface states with very similar densities at  $\text{Al}_2\text{O}_3/\text{AlGaIn}$  and  $\text{AlTiO}/\text{AlGaIn}$ . From the peaks, we can obtain the relationship between  $D_i$  and  $\tau$ . Moreover,  $\tau$  for an interface state at the energy  $E$  is given by  $\tau = \tau_0 \exp[(E_C - E)/k_B T]$  using the Boltzmann constant  $k_B$ , temperature  $T$ , and the conduction band bottom energy  $E_C$ , where  $\tau_0$  is a time constant determined by the capture cross section of the trap. Thus, using  $\tau_0$ , we can estimate the relationship between  $D_i$  and  $(E_C - E)$ . Even though  $\tau_0$  is ambiguous, assuming a wide range of  $\tau_0 = 1\text{--}100$  ps, we show  $D_i$  as functions of  $(E_C - E)$  in Fig. 10(b), where the error bars correspond to the wide range of  $\tau_0$  values. This indicates a very similar shallow interface state density  $D_i \sim 2 \times 10^{13} \text{ cm}^{-2} \text{ eV}^{-1}$  of  $\text{Al}_2\text{O}_3/\text{AlGaIn}$  and  $\text{AlTiO}/\text{AlGaIn}$  and suggests that deep interface state densities are also similar, even though the interface fixed charge density  $\sigma_{\text{ins}}$  is rather lower at  $\text{AlTiO}/\text{AlGaIn}$ . Thus, we should conclude that there is no correlation between the interface fixed charges and the interface states in our case, as reported in Ref. 32. This suggests that the lower  $\sigma_{\text{ins}}$  at  $\text{AlTiO}/\text{AlGaIn}$  is not owing to electrons trapped at deep interface states, compensating the positive fixed charges. Since interface states generally have a U-shaped density of states, from the shallow interface state density above, we can expect a deep interface state density of  $\leq 10^{13} \text{ cm}^{-2} \text{ eV}^{-1}$  or less. On the other hand, the difference between  $\sigma_{\text{ins}}/q$  at  $\text{Al}_2\text{O}_3/\text{AlGaIn}$  and that at  $\text{AlTiO}/\text{AlGaIn}$  is  $\sim 0.8 \times 10^{13} \text{ cm}^{-2}$ . Thus, it is not plausible that the difference is due to trapped electrons at the deep interface states. Although the material origin of the lower  $\sigma_{\text{ins}}$  at  $\text{AlTiO}/\text{AlGaIn}$  is not clear, it is possible to tentatively assume a lower density of oxygen-related interface donors, where strong Ti-O bonding may suppress donor formation.

## V. CONCLUSION

We have investigated insulator-semiconductor interface fixed charges in  $\text{Al}_2\text{O}_3/\text{AlGaIn}/\text{GaIn}$  and  $\text{AlTiO}/\text{AlGaIn}/\text{GaIn}$  MIS devices. The  $\text{AlTiO}/\text{AlGaIn}$  interface gives significantly lower-density interface fixed charges and rather shallower threshold voltages. The lower interface fixed charge density also leads to the fact that the 2DEG concentration is a decreasing function of the  $\text{AlTiO}$  thickness, whereas being an increasing function of the  $\text{Al}_2\text{O}_3$  thickness. Moreover, we discuss the relationship between the interface fixed charges and interface states. Since the interface state densities are very similar at  $\text{Al}_2\text{O}_3/\text{AlGaIn}$  and  $\text{AlTiO}/\text{AlGaIn}$ , it is suggested that the lower interface fixed charge density at  $\text{AlTiO}/\text{AlGaIn}$  is not owing to electrons trapped at deep interface states, compensating the positive fixed charges. Thus, a lower density of oxygen-related donors at the  $\text{AlTiO}/\text{AlGaIn}$  interface can be assumed, where strong Ti-O bonding may suppress donor formation. We consider that the results can provide a clue towards  $V_{\text{th}}$  control and normally off operations of GaN-based MIS devices.
