Abstract

TiO$_2$ nanoparticles modified with composite nanoclusters of 9-mesityl-10-carboxymethylacridinium ion (Mes-Acr$^+$-COOH) and fullerene (C$_{60}$) in acetonitrile/toluene (3:1, v/v) were deposited as thin films on nanostructured SnO$_2$ electrode using an electrophoretic technique. The composite TiO$_2$ films have broad as well as high absorbance properties, exhibiting photoactive response under visible light excitation using I$_3$/I$^-$ redox couple as compared with the reference multilayer films composed of the single component. This indicates that the composite cluster TiO$_2$ film based on 9-mesityl-10-carboxymethylacridinium ion and fullerene harvests light widely in the visible region due to organization of the supramolecular assembly. In the case of a monolayer system of TiO$_2$ nanocrystallites modified with Mes-Acr$^+$-COOH, however, no net photocurrent is observed in the photocurrent action spectrum. This indicates that TiO$_2$ nanoparticles act as materials to organize composite molecules rather than as those to accept electrons. An incident photon-to-photocurrent generation efficiency (IPCE) of 37% has been achieved at an applied bias potential of 0.2 V vs. SCE in the Mes-Acr$^+$-COOH/C$_{60}$ composite system using TiO$_2$ nanoparticles.
Introduction

Self-assembly is the autonomous organization of components into patterns or structures, and its processes are common throughout nature and technology.\textsuperscript{1} Molecular assembly involves a variety of interactions, presenting unique characteristics which has hardly appeared in a single molecule.\textsuperscript{1-3} Hydrogen bonding, van der Waals interaction, and hydrophobic effects are the major driving force to achieve such ordered molecular assembly.\textsuperscript{4,5} Of particular interest is the ability of such assembly in protein matrix to mimic the energy and electron-transfer processes in the photosynthetic reaction center.\textsuperscript{6,7}

In the past two decades, extensive endeavors have been devoted to develop molecular donor-acceptor systems (triads, tetrad, pentads, etc.), which can mimic a cascade of electron-transfer steps in the natural photosynthetic reaction center, leading to long-range charge separation with prolonged lifetime of the charge-separated state into second range.\textsuperscript{8-12} However, the synthetic difficulty has precluded application of such artificial photosynthetic model compounds to develop low-cost photovoltaic devices.\textsuperscript{13-15} In addition, a significant amount of energy is lost during the multi-step electron-transfer processes in both natural and artificial long-range charge separation. Avoidance of such wasted energy loss and high-cost multi-step synthesis is certainly required for development of low-cost efficient molecular devices. In this context, we have recently designed and synthesized a simple dyad (9-mesityl-10-methylacridinium ion) which exhibits extremely slow charge-recombination of the electron-transfer state with remarkably high energy (2.37 eV).\textsuperscript{16} Such a simple molecular dyad capable of fast charge separation, but extremely slow charge recombination, has obvious advantages with regard to synthetic feasibility.
On the other hand, the requirement to develop inexpensive renewable energy sources has stimulated new approaches for production of efficient, low-cost organic photovoltaic devices. In the recent year particular attention has been drawn towards developing of bulk heterojunction organic solar cells, which possess an active layer of a conjugated donor polymer and an acceptor fullerene. Fullerene is suitable as an electron acceptor component in such organic solar cells, since electron-transfer reduction of C60 is highly efficient because of the minimal changes of structure and solvation associated with the electron-transfer reduction. In addition, we have recently reported light energy conversion systems based on composite molecular clusters of electron donor moiety and acceptor fullerene by electrophoretic deposition methods. These reports clearly demonstrate that three dimensional control between donor and acceptor moieties in multilayer films has great effect on the light energy conversion property. The electrophoretic deposition methods of dye-adsorbed TiO2 nanoparticles on electrodes has also been reported to be useful for preparation of organic thin films to obtain good electron acceptor materials. However, the utilization of TiO2 nanoparticles for three dimensional control in organization of donor-acceptor composite molecules has yet to be reported.

We report herein a new type of organic solar cells based on TiO2 nanoparticles modified with supramolecular self-assembly clusters of 9-mesityl-10-carboxymethylacridinium ion (Fig. 1) and fullerene, which are deposited as thin films on optically transparent electrode (OTE) of nanostructured SnO2 (OTE/SnO2) using an electrophoretic method. 9-Mesityl-10-methylacridinium ion (Mes-Acr+), which exhibits slow charge-recombination of the electron-transfer state with remarkably high energy, is modified with carboxylic acid group (Mes-Acr+-COOH in Fig. 1) to be assembled on TiO2 nanoparticles [denoted as Mes-Acr+-COO-TiO2 in Fig. 1]. The photoelectrochemical performance of nanostructured SnO2 film of TiO2 nanoparticles modified with composite clusters of Mes-Acr+-COOH and fullerene
[denoted as OTE/SnO$_2$/(Mes-Acr$^+$-COO-TiO$_2$+C$_{60}$)$_n$] is significantly superior to the single component films of an individual component. The morphology and the photocurrent generation mechanism of OTE/SnO$_2$/(Mes-Acr$^+$-COO-TiO$_2$+C$_{60}$)$_n$ are reported in full detail in this paper.

Fig. 1

**Experimental Section**

**General.** Chemicals used in this study are of the best grade available, supplied by Tokyo Chemical Industries, Wako Pure Chemical, or Sigma Aldrich Co. $^1$H NMR spectra were recorded on a JNM-AL300 (JEOL) instrument at 300 MHz. Matrix-assisted laser desorption/ionization (MALDI) time-of-flight (TOF) mass spectra were measured on a Kratos Compact MALDI I (Shimadzu). TiO$_2$ nanoparticles (P25, $d = 21$ nm) were purchased from Nippon Aerogel Co. Preparation of 9-mesityl-10-carboxymethylacridinium ion (Mes-Acr$^+$-COOH) has been described elsewhere,$^{23d}$ and the synthetic procedure of the reference compound (Acr$^+$-COOH in Fig. 1) is described in electronic supplementary information (ESI).

**Preparation of TiO$_2$ nanoparticles modified with the dye moieties (Mes-Acr$^+$-COO-TiO$_2$ and Acr$^+$-COO-TiO$_2$).** Mes-Acr$^+$-COO-TiO$_2$ and Acr$^+$-COO-TiO$_2$ were prepared by immersing warmed TiO$_2$ nanoparticles (80~100 °C) in a acetonitrile mixture (10 ml) containing 3.0 × 10$^{-4}$ mol dm$^{-3}$ of Mes-Acr$^+$-COOH and Acr$^+$-COOH for 12 h, respectively. After adsorbing Mes-Acr$^+$-COOH and Acr$^+$-COOH, TiO$_2$ nanoparticles were filtered, and the subsequent washing with acetonitrile and drying gave Mes-Acr$^+$-COO-TiO$_2$ and Acr$^+$-COO-TiO$_2$. The dye molecule was completely desorbed from TiO$_2$ particles into solution by immersing the TiO$_2$ nanoparticles modified with the dye moieties in methanol overnight. The
amounts of \textit{Mes-Acr}^{+}-\text{COOH} and \textit{Acr}^{+}-\text{COOH} adsorbed on TiO$_2$ nanoparticles relative to the total weight were determined as 1.5 $\times$ 10$^{-5}$ and 1.5 $\times$ 10$^{-5}$ mol/g, respectively.

\textbf{Electrophoretic deposition of composite clusters on electrode.} C$_{60}$ is soluble in nonpolar solvents such as toluene. In mixed solvents (acetonitrile/toluene), however, they aggregate to form large size clusters of diameter 100 nm - 300 nm.$^{25}$ The C$_{60}$ cluster and TiO$_2$ nanoparticles were electrophoretically deposited onto SnO$_2$ films under applied voltage as reported previously.$^{23,25}$

Nanostructured SnO$_2$ films were cast on an optically transparent electrode (OTE) by applying a dilute (1-2\%) colloidal solution (Alfa Chemicals), followed by annealing the dried film at 673 K. Details about the electrode preparation and its properties have been described elsewhere.$^{26}$ These films are highly porous and electrochemically active to conduct charges across the film. The SnO$_2$ film electrode (OTE/SnO$_2$) and an OTE plate were introduced in a 1 cm path length cuvette and they were connected to positive and negative terminals of the power supply, respectively. A known amount (~2 mL) of C$_{60}$, \textit{Mes-Acr}^{+}-\text{COO-TiO$_2$}, or the mixed cluster suspension in acetonitrile/toluene (3/1, v/v) immediately after the ultrasonication was transferred to a 1 cm cuvette in which two electrodes (viz., OTE/SnO$_2$ and OTE) were kept at a distance of ~6 mm using a Teflon spacer. A dc voltage (500V) for 2 minutes was applied between these two electrodes using a Fluke 415 power supply. The deposition of the film can be visibly seen as the solution becomes colorless with simultaneous brown coloration of the SnO$_2$/OTE electrode. The SnO$_2$/OTE electrode coated with mixed \textit{Mes-Acr}^{+}-\text{COO-TiO$_2$} and C$_{60}$ clusters is referred to OTE/SnO$_2$/\textit{(Mes-Acr}^{+}-\text{COO-TiO$_2$}+C$_{60}$)$_n$.  

SnO$_2$ nanocrystallites films modified with \textit{Mes-Acr}^{+}-\text{COOH} (denoted as OTE/SnO$_2$/\textit{Mes-Acr}^{+}-\text{COOH}) is the following. The synthesized dyad (\textit{Mes-Acr}^{+}-\text{COOH}) was adsorbed by immersing OTE/SnO$_2$ electrode in a 2 $\times$ 10$^{-3}$ mol dm$^{-3}$
ethanol solution overnight to prepare OTE/SnO₂/Mes-Acr⁺-COOH electrode. In order to remove the adsorbed water from the SnO₂ surface, the films were heated to 80 °C before the immersion. TiO₂ nanocrystallites films modified with Mes-Acr⁺-COOH (denoted as OTE/TiO₂/Mes-Acr⁺-COOH) is described in ESI.

The UV-visible spectra were recorded on a Shimadzu 3101 spectrophotometer. Images were recorded using a Hitachi H600 transmission electron microscope. The morphology of the mesoporous electrodes was characterized by a scanning electron micrograph (SEM; JEOL, JSM-6700FE). The SEM was operated with an accelerating voltage of 10 kV.

**Photoelectrochemical measurements.** Photoelectrochemical measurements were performed using a standard three-compartment cell consisting of a working electrode and Pt wire gauze counter electrode and saturated calomel reference electrode (SCE). All photoelectrochemical measurements were carried out in acetonitrile containing 0.5 mol dm⁻³ NaI and 0.01 mol dm⁻³ I₂ with a Keithley model 617 programmable electrometer. A collimated light beam from a 150 W Xenon lamp with a 400 nm cut-off filter was used for excitation of the composite cluster films cast on SnO₂ electrodes. A Bausch and Lomb high intensity grating monochromator was introduced into the path of the excitation beam for selecting wavelength. A Princeton Applied Research (PAR) model 173 potentiostat and Model 175 universal programmer were used for recording I-V characteristics.

**Transient absorption measurements.** Nanosecond laser flash photolysis experiments were performed using a Spectra Physics model PR0230 laser system (355 nm, 10 ns pulse width, 40 mJ/pulse). The laser output was suitably attenuated to about 20 mJ/pulse and defocused to minimize the multiphoton process. The measurements were performed in a rectangular quartz cell of 6 mm path length with a right angle configuration between the direction of laser excitation and analyzing light. The photomultiplier output was digitized with a Tektronix 7912 AD programmable
Results and discussion

Preparation of the composite cluster film composed of Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} and C\textsubscript{60} by electrophoretic deposition. TiO\textsubscript{2} nanoparticles were electrophoretically deposited onto the electrode in suspended solution.\textsuperscript{24} On the other hand, C\textsubscript{60} is soluble in nonpolar solvents such as toluene, but less so in polar solvents such as acetonitrile.\textsuperscript{25} By the proper choice of polar to nonpolar solvent, we can achieve a controlled aggregation in the form of C\textsubscript{60} nanoclusters. Unless otherwise noted we maintained a final solvent ratio of 3:1 (v/v) acetonitrile : toluene to prepare C\textsubscript{60} nanoclusters. Detail information of C\textsubscript{60} nanocluster is described elsewhere.\textsuperscript{25} A mixed cluster suspension of Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} and C\textsubscript{60} was prepared in the total concentration range from 0.025 to 0.13 mmol dm\textsuperscript{-3} (molecular ratio of Mes-Acr\textsuperscript{+}:C\textsubscript{60} = 1:5) in acetonitrile/toluene (3/1, v/v).

As shown earlier,\textsuperscript{23} clusters suspended in acetonitrile/toluene mixed solvent can be assembled electrophoretically as thin films on a conducting glass electrode surface. A similar electrodeposition approach was adopted to prepare films of (Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2}+C\textsubscript{60})\textsubscript{n} on nanostructured SnO\textsubscript{2} films cast on an optically conducting glass electrode. Upon application of the DC electric field of 500 V between OTE/SnO\textsubscript{2} and OTE electrodes which were immersed parallel in a mixed acetonitrile/toluene (3/1, v/v) solution containing (Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2}+C\textsubscript{60})\textsubscript{n} clusters, we can achieve deposition of mixed clusters on a nanostructured SnO\textsubscript{2} electrode. As the deposition continues we can visually observe discoloration of the solution and coloration of the electrode that is connected to positive terminal of the dc power supply.
Fig. 2a shows that the absorption spectrum of the OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} +C\textsubscript{60})\textsubscript{n} electrode prepared using different precursor concentrations of Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} and C\textsubscript{60} in acetonitrile/toluene (3/1, v/v) mixture. Note that the mixed clusters were first prepared using different amounts of Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} and C\textsubscript{60} to maintain their molar ratio as 1:5. An increase in the absorbance of the OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} +C\textsubscript{60})\textsubscript{n} electrode in the visible and near-infrared regions is clearly observed as compared with those of individual component: OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2})\textsubscript{n} (Fig. 2b) and OTE/SnO2/(C\textsubscript{60})\textsubscript{n} (Fig. 2c), which were prepared under the same experimental condition. In addition, the spectrum of the OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2})\textsubscript{n} film has much broader as well as higher absorption than that of the monolayer film: OTE/SnO2/Mes-Acr\textsuperscript{+}-COOH (Fig. 2d). This indicates that the multilayer film of Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} using an electrophoretic deposition method exhibits a high absorption property in the all visible region. This broad absorption of OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2})\textsubscript{n} may be ascribed to strong interaction in the molecular assembly.\textsuperscript{27} Furthermore, broader wavelength absorption in the OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} +C\textsubscript{60})\textsubscript{n} film relative to those in the OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2})\textsubscript{n} and OTE/SnO2/(C\textsubscript{60})\textsubscript{n} films may be diagnostic of charge-transfer (CT) absorption band between Mes-Acr\textsuperscript{+} moiety and fullerene since a similar broad absorption, which is characteristic of an intermolecular CT band,\textsuperscript{28} is also observed in solution (See ESI).

**Fig. 2**

**Morphology of OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} +C\textsubscript{60})\textsubscript{n}.** Scanning electron micrograph (SEM) was used to evaluate the morphology of the OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} +C\textsubscript{60})\textsubscript{n} film and the reference film (OTE/SnO2/(C\textsubscript{60})\textsubscript{n}) as shown in Fig. 3. The OTE/SnO2/(Mes-Acr\textsuperscript{+}-COO-TiO\textsubscript{2} +C\textsubscript{60})\textsubscript{n} film is composed of closely
packed clusters of about 20-100 nm size with a networked structure. This structure may result from a supramolecular interaction between Mes-Acr⁺-COO-TiO₂ and C₆₀ in the TiO₂ nanoparticle matrix. On the other hand, the OTE/SnO₂/(C₆₀)ₙ films contain a large size (100 – 300 nm) of nanoclusters in contrast with the size of the OTE/SnO₂/(Mes-Acr⁺-COO-TiO₂+C₆₀)ₙ film. This cluster size is in good agreement with our previous result of AFM images.²⁵a Based on these SEM images we can conclude that TiO₂ nanoparticles play an important role in the cluster formation on the films.

Fig. 3

**Light energy conversion properties.** Photocurrent measurements were performed using the OTE/SnO₂/(Mes-Acr⁺-COO-TiO₂+C₆₀)ₙ electrode as a photoanode in acetonitrile containing NaI (0.5 mol dm⁻³) and I₂ (0.01 mol dm⁻³), which act as redox electrolyte, and a Pt gauge counter electrode. The photovoltage and photocurrent responses recorded following the excitation of the OTE/SnO₂/(Mes-Acr⁺-COO-TiO₂+C₆₀)ₙ electrode at the visible light region (λ > 400 nm) are shown in Fig. 4A and B, respectively. The photocurrent response is prompt, steady and reproducible during repeated on/off cycles of the visible light illumination. The short circuit photocurrent density (Iₛ𝚌) is 0.093 mA/cm², and the open circuit voltage (Vₒ∞) is 200 mV. Blank experiments conducted with OTE/SnO₂ (i.e., by excluding composite clusters (Mes-Acr⁺-COO-TiO₂+C₆₀)ₙ produced no detectable photocurrent under otherwise the same experimental conditions. These experiments confirmed the important role of (Mes-Acr⁺-COO-TiO₂+C₆₀)ₙ assembly in harvesting light energy and also in generating photocurrent during the operation of the photoelectrochemical cell.
The charge separation on the OTE/SnO$_2$/(Mes-Acr$^+$-COO-TiO$_2$+C$_{60}$)$_n$ electrode can be further modulated by the application of an electrochemical bias. Fig. 5 shows I-V characteristics of the OTE/SnO$_2$/(Mes-Acr$^+$-COO-TiO$_2$+C$_{60}$)$_n$ electrode under the visible light illumination. The photocurrent increases as the applied potential is scanned towards more positive potentials. Increased charge separation and the facile transport of charge carriers under a positive bias are responsible for the enhanced photocurrent generation.$^{23a}$ At potentials greater than +0.4 V vs. SCE direct electrochemical oxidation of iodide interferes with the photocurrent measurement.

A series of photocurrent action spectra were recorded in order to evaluate the response of (Mes-Acr$^+$-COO-TiO$_2$+C$_{60}$)$_n$ clusters towards the photocurrent generation. It should be noted that no net photocurrent is observed through the visible region in the photocurrent action spectrum of TiO$_2$ nanocrystallites films modified with Mes-Acr$^+$-COOH (denoted as OTE/TiO$_2$/Mes-Acr$^+$-COOH); see ESI. Since the one-electron reduction potential of acridinium ion (Acr$^+$/Acr$^*$) (-0.3 V vs. NHE) is less negative than the conduction band of TiO$_2$ (-0.5 V vs. NHE), electron transfer from Acr$^*$ to the conduction band of TiO$_2$ is thermodynamically unfavorable. Thus, TiO$_2$ nanoparticles act as materials to organize composite molecules rather than as those to accept electrons. The photocurrent action spectrum of the OTE/SnO$_2$/(Mes-Acr$^+$-COO-TiO$_2$+C$_{60}$)$_n$ electrode produced by the electrodeposition of Mes-Acr$^+$-COO-TiO$_2$ and C$_{60}$ ([Mes-Acr$^+$] = 0.025 mmol dm$^{-3}$, [C$_{60}$] = 0.13 mmol dm$^{-3}$) is shown in Fig. 6A. The IPCE values were calculated by normalizing the photocurrent values for incident light energy and intensity and using eqn. (1),$^{23a}$
IPCE (%) = 100 × 1240 × \( \frac{I_{sc}}{W_{in} \times \lambda} \)  \hspace{1cm} (1)

where \( I_{sc} \) is the short circuit photocurrent (A/cm\(^2\)), \( W_{in} \) is the incident light intensity (W/cm\(^2\)), and \( \lambda \) is the wavelength (nm).

**Fig. 6**

The maximum IPCE value of OTE/SnO\(_2\)/Mes-Acr\(^+\)-COOH (spectrum a in Fig. 6A) is only 2% (445 nm), whereas the IPCE value of OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\))\(_n\) (spectrum b) reaches 5% (480 nm). In addition, the IPCE values of the OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrode (spectrum c) are much higher than the sum (spectrum e) of two individual IPCE values of OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\))\(_n\) (spectrum b) and OTE/SnO\(_2\)/(C\(_{60}\))\(_n\) (spectrum d) in the visible region. This indicates that the supramolecular complexes formed between Mes–Acr\(^+\) and C\(_{60}\) with TiO\(_2\) nanoparticles contribute significantly to the efficient photocurrent generation.\(^{23}\)

In order to further clarify the effect of the supramolecular complex with TiO\(_2\) nanoparticles on the photocurrent generation, we compared the photocurrent action spectrum of the OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrode with those of OTE/SnO\(_2\)/(C\(_{60}\))\(_n\) and OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\))\(_n\) electrodes in a standard three-compartment cell under the bias of 0.2 V vs. SCE (Fig. 6B).\(^{23a}\) The photocurrent action spectrum of the OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrode shows a maximum IPCE value of 37% at an applied potential of 0.2 V vs. SCE (spectrum a in Fig. 6B). Under same experimental conditions we observe much smaller IPCE values for the single component systems, viz., OTE/SnO\(_2\)/(C\(_{60}\))\(_n\) and OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\))\(_n\) (spectra b and c in Fig. 6B, respectively). The IPCE value obtained with the mixed cluster system (37%), viz. OTE/SnO\(_2\)/(Mes-
Acr\(^{+}\)-COO-TiO\(_2\)(C\(_{60}\))\(_n\) is larger than the sum of two individual IPCE values (~11%). Such enhancement in the photocurrent generation of the composite cluster systems of Mes-Acr\(^{+}\)-COO-TiO\(_2\) and C\(_{60}\) as compared with the single component systems may result from interplay between Mes-Acr\(^{+}\)-COO-TiO\(_2\) and C\(_{60}\) in the supramolecular complex.

We have also compared photocurrent action spectra of the OTE/SnO\(_2\)/(Acr\(^{+}\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrode (Fig. 6C), in which acridinium moiety (Acr\(^{+}\)) contains no donor moiety, with that of the OTE/SnO\(_2\)/(Mes-Acr\(^{+}\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrode. The maximum IPCE value of the OTE/SnO\(_2\)/(Acr\(^{+}\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrode in standard two (no bias) and three (0.2 V vs. SCE) compartment cells (vide supra) reached 7 and 14\%, respectively. These IPCE values are significantly smaller than those of the OTE/SnO\(_2\)/(Mes-Acr\(^{+}\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrodes (respective values: 13\% and 37\%). This indicates that photoinduced electron transfer from the donor moiety (Mes) to the acceptor moiety (Acr\(^{+}\)) occurs, followed by electron transfer from the resulting acridinyl radical moiety (Acr\(^{−}\)) to C\(_{60}\) in the supramolecular complex, leading to enhance the photocurrent generation.

**Electron transfer in the supramolecular complex.** In order to confirm the occurrence of photoinduced electron transfer from the Mes moiety to the Acr\(^{+}\) moiety and subsequent electron transfer from the resulting acridinyl radical moiety (Acr\(^{−}\)) to C\(_{60}\) in the supramolecular complex, we examined formation of C\(_{60}\) radical anion in the nanosecond laser flash photolysis measurements of deoxygenated toluene-acetonitrile (1:1, v/v) solution of 9-mesityl-10-methylacridinium ion without carboxylic acid (Mes-Acr\(^{+}\))\(^{16}\) in the presence of C\(_{60}\). The time-resolved transient absorption spectra are shown in Fig. 7A, which clearly exhibits a broad absorption band at about 1050 nm. This is diagnostic of formation of C\(_{60}\) radical anion upon photoirradiation.\(^{29-31}\) Thus, electron transfer indeed occurs from the acridinyl radical moiety (Acr\(^{−}\)) to C\(_{60}\), following photoinduced electron transfer from the Mes moiety.
to the singlet excited state of Acr\(^+\) moiety of Mes-Acr\(^+\) to produce the electron-transfer state: Mes\(^{++}\)-Acr\(^-\), which is known to have an extremely long lifetime.\(^{16}\) The absorption time profile of the composite cluster (Mes-Acr\(^+\) dyad and C\(_{60}\)) in deoxygenated toluene-acetonitrile (1:1) recorded at 1050 nm is shown in Fig. 7B.\(^{31}\) The observed second-order decay kinetics (inset of Fig. 7B) corresponds to back electron transfer from C\(_{60}\)\(^-\) to the Mes\(^{++}\) moiety of Mes\(^{++}\)-Acr\(^+\), affording the second-order rate constant of the back electron transfer (\(k_{\text{bet}} = 2.9 \times 10^9\) dm\(^3\) mol\(^{-1}\) s\(^{-1}\)).

**Fig. 7**

**Photocurrent generation mechanism.** Mechanisms of the photocurrent generation of OTE/SnO\(_2\)/(C\(_{60}\))\(_n\), OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\))\(_n\), and OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrodes are summarized in Scheme 1, 2 and 3, respectively. In the case of the OTE/SnO\(_2\)/(C\(_{60}\))\(_n\) electrode (Scheme 1), photoinduced electron transfer between iodide ion and the excited state of C\(_{60}\) clusters is the primary step in the photocurrent generation.\(^{23a,25b,32}\) The reduced C\(_{60}\) then injects electrons into SnO\(_2\) nanocrystallites. Such a mechanism involving generation of electroactive species (C\(_{60}\) anion in the present case) is commonly operative in photogalvanic type solar cells.\(^{23,25}\) In the case of the OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\))\(_n\) electrode (Scheme 2), however, the photocurrent generation is initiated by photoinduced electron transfer in Mes-Acr\(^+\) to produce Mes\(^{++}\)-Acr\(^-\). The reduced acridinium ion (Acr\(^-\); \(E^0(Acr^+/Acr^-) = -0.3\) V vs NHE)\(^{16}\) injects electrons into the conduction band of SnO\(_2\) (\(E^0 = 0\) V vs NHE),\(^{23a}\) whereas the oxidized mesityl moiety (Mes\(^{++}\); \(E^0(Mes^{++}/Mes) = 2.0\) V vs NHE)\(^{16}\) undergoes the electron-transfer reduction with iodide ion (\(E^0(I^-/I^-) = 0.5\) V vs NHE)\(^{23a}\) in the electrolyte solution.

\]

Scheme 2. Photocurrent generation diagram at the OTE/SnO$_2$/(Mes-Acr$^+$-COO-TiO$_2$)$_n$ electrode

\[
\text{OTE/SnO}_2/(\text{Mes-Acr}^+\text{-COO-TiO}_2)_n \xrightarrow{hv} \text{OTE/SnO}_2/(\text{Mes}^{++}\text{-Acr}^-\text{-COO-TiO}_2)(\text{Mes-Acr}^+\text{-COO-TiO}_2)_{n-1} \\
\text{OTE/SnO}_2/(\text{Mes-Acr}^+\text{-COO-TiO}_2)_{n-1} \xrightarrow{l^+ + l^-} \text{OTE/SnO}_2/(\text{Mes-Acr}^+\text{-COO-TiO}_2)_{n-1} \xrightarrow{l^- + l^-} \text{OTE/SnO}_2/(\text{Mes-Acr}^+\text{-COO-TiO}_2)_{n-1}
\]

In the case of the OTE/SnO$_2$/(Mes-Acr$^+$-COO-TiO$_2$+C$_{60}$)$_n$ electrode (Scheme 3), the long lifetime of the electron-transfer state (Acr$^+$-Mes$^{++}$) ensures efficient electron-transfer from Acr$^+$ to C$_{60}$ (C$_{60}$/C$_{60}$$^-$ = -0.2 V vs NHE)$^{23a}$ to produce C$_{60}$ radical anion (vide supra). The reduced C$_{60}$ clusters inject electrons into the conduction band of SnO$_2$, whereas the oxidized mesityl moiety (Mes$^{++}$) undergoes the electron-transfer reduction with iodide ion in the electrolyte. The effect of C$_{60}$ on the enhanced photocurrent generation cannot be ascribed to the thermodynamics of electron injection process. The enhanced IPCE value at the absorption band due to the Acr$^+$ moiety by the presence of C$_{60}$ results from fast self-exchange electron transfer between C$_{60}$$^-$ and C$_{60}$,$^{29,33}$ which leads to efficient photocurrent generation, since the singlet excited state of the Acr$^+$ moiety is mostly quenched by the Mes moiety.
**Scheme 3.** Photocurrent generation diagram at the OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrode

followed by electron transfer from the resulting Acr\(^+\) moiety to C\(_{60}\). Enhanced IPCE values of the OTE/SnO\(_2\)/(Mes-Acr\(^+\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrode (spectrum c in Fig. 6A) compared to the sum of two IPCE values of the corresponding single component systems (spectrum e in Fig. 6A) in the long wavelength region over 500 nm may result from charge-transfer (CT) interaction between the Mes (donor) moiety of Mes-Acr\(^+\)-COOH and C\(_{60}\) clusters (See ESI).

**Power conversion efficiency.** We have also determined the power conversion efficiency (\(\eta\)) of the photoelectrochemical cell by varying the load resistance (Fig. 8). Power conversion efficiency, \(\eta\) is calculated by eqn. (2),\(^{23a}\)

\[
\eta = ff \times I_{sc} \times V_{oc}/W_{in}
\]  

(2)

where the fill factor (ff) is defined as \(ff = P_{max}/(V_{oc} \times I_{sc})\); \(P_{max}\) is the maximum power output of the cell, \(V_{oc}\) is open circuit photovoltage, \(I_{sc}\) is the short circuit photocurrent. A decrease in the photovoltage accompanied by an increase in the photocurrent is observed with decreasing the load resistance (Fig. 8). The ff value of the (Mes-Acr\(^+\)-COO-TiO\(_2\)+C\(_{60}\))\(_n\) electrode is determined as 0.38. Net power conversion efficiency obtained for the same cell was 0.11% at input power of 6.5 mW/cm\(^2\).\(^{34}\)
Conclusion

We have successfully constructed supramolecular photovoltaic composed of composite molecular nanocluster assemblies of fullerene and a simple molecular dyad (Mes-Acr\(^+\)-COOH) with an extremely long lifetime and a high energy of the electron-transfer state, which is efficiently organized using TiO\(_2\) nanoparticles. Remarkable improvement in the photoelectrochemical properties of the composite of Mes-Acr\(^+\)-COOH and C\(_{60}\) nanoclusters has been achieved as compared with the corresponding single component systems (OTE/SnO\(_2\)/(C\(_{60}\))\(_n\) and OTE/SnO\(_2\)/([Mes-Acr\(^+\)-COO-TiO\(_2\)])\(_n\)), due to the effective organization of the supramolecular complex on TiO\(_2\) nanoparticles, the extremely long lifetime of the electron-transfer state of Mes-Acr\(^+\)-COOH, and efficient electron transfer from Acr\(^+\) to C\(_{60}\).

References and Notes

30. The extinction coefficient of $C_{60}^-$ has been reported as $12000 \text{ M}^{-1}\text{ cm}^{-1}$. See: D. R. Lawson, D. L. Feldheim, C. A. Foss, P. K. Dorhout, C. M. Elliott, C. R. Martin and B. Parkinson, *J. Electrochem. Soc.*, 1992, **139**, L68.

31. The transient absorption band at the NIR region (1050 nm) is clearly assigned to the $C_{60}$ cluster radical anion since such an NIR absorption band is diagnostic of $C_{60}$ radical anion ($C_{60}^-$). The small difference in the $\lambda_{\text{max}}$ value (1050 nm) in Fig. 7A from that of $C_{60}^-\text{ (1080 nm)}$ results from the molecular aggregation of the cluster radical anion (see: ref 30). The $\lambda_{\text{max}}$ values of absorption spectra of $C_{60}^-$ slightly vary depending on the molecular assembly property.

32. Judging from the large driving force of photoinduced electron transfer from $\Gamma^-$ to the singlet excited state of $C_{60}$ (1.3 eV), the photoinduced electron transfer may occur at the diffusion-limited rate. In such a case, the concentration of $\Gamma^-$ (0.50 mol dm$^{-3}$) is large enough to quench the singlet excited state of $C_{60}$ by the
electron transfer reduction of $\Gamma^-$. The electron transfer from $\Gamma^-$ to the triplet excited state of $C_{60}$ is also exergonic ($\Delta G = -0.9$ V) and thus both the singlet and triplet excited states of $C_{60}$ may be involved in the photoinduced electron transfer reduction of $\Gamma^-$. The excitation energy of singlet and triplet excited states of $C_{60}$ has been reported as 1.99 and 1.57 eV, respectively. See: R. M. Williams, J. M. Zwier and J. W. Verhoeven, *J. Am. Chem. Soc.*, 1995, **117**, 4093.

34. The power conversion efficiency at high input power (100 mW/cm$^2$) decreases to 0.055%.
